## Abstract

In the last decades, processed animal proteins, such as poultry by-product meal (PBM) and insect meals have received great attention as sustainable and nutritious aquafeed ingredients. The aim of the present study was to evaluate growth performances, liver and gut histology, macromolecular composition and inflammatory response in rainbow trout (*Oncorhynchus mykiss*) fed diets deprived of fish meal, where graded levels of vegetable protein-rich ingredients, were replaced by defatted *Hermetia illucens* pupae meal (HM) or PBM, singly or in combination. To this end eight grossly iso-proteic (45% DM), iso-lipidic (26% DM) and iso-energetic (23.5 MJ/kg DM) were offered each to triplicated groups of juveniles' fish in 91 days feeding trial. A diet rich in vegetable protein derivatives high in soybean meal (CV) was prepared to have a 10:90 and 20:80 fish to vegetable protein and lipid ratios respectively. By contrast, a fish-based diet (CF) was formulated with opposite fish to vegetable protein and lipid ratios. Six more diets, were obtained by replacing graded levels of protein (10, 30 and 60%) of diet CV, by protein from a defatted *Hermetia illucens* pupae meal and/or poultry by-product meal, singly or combined, while maintaining the same vegetable to fish lipid ratio as in the CV diet. Relative to diets CV and CF, a medium to high substitution (30 and 60%) of dietary vegetable protein-rich ingredients, with HM and/or PBM resulted in improved growth performance as well as in a minor incidence of distal intestine morphological alterations. The diet including both the test animal proteins led to nearly the best overall response in terms of growth and gut/liver health. Both HM and PBM when included at moderate or high levels in the diet, resulted in a downregulation of the expression of inflammatory-related genes relative to diet CV. This effect was greater with HM than that observed with PBM and goes beyond the parallel reduction of vegetable protein and SBM levels in the same diets, suggesting a beneficial role of insect meal that warrant further investigation. The results obtained so far, provide support to a reliable use of alternative/underexploited protein and lipid sources [(HM) or (PBM)] in developing a new generation of sustainable and healthy trout diets that meet the circular economy principles.

**Key words:** rainbow trout, new diets, insect meal, poultry by-product meal, vegetable proteins, fish physiology, gut health

## 1. Introduction

It is generally agreed that any further growth of the aquaculture industry, could greatly benefit from a new generation of diets inclusive of nutritious, healthy, cost-effective and environmentally sustainable feed ingredients. In this direction, in recent years, the readily available and/or cost-effective plant protein-rich feeds and derivatives, such as oilseed meals, cereal glutens, protein concentrates and pulses, became major protein sources in aquafeeds mostly substituting fish meal (FM) (Gatlin et al., 2007). On the other hand, many studies have shown that fish responses to diets including high levels of plant protein-rich ingredients such as soybean meal (SBM) is often species-specific, depending on the life stage, the nutritional/anti-nutritional properties and the dietary inclusion levels. Adverse effects were described in salmonids in terms of reduced feed intake, nutrient-energy digestibility and retention which in turn impaired the growth performance (Collins et al., 2013). In salmonids, several studies have shown that high dietary inclusion levels of SBM often caused non-infectious enteritis onset in the distal intestine (Baeverfjord and Krogdahl, 1996; Penn et al., 2011; Krogdahl et al., 2015) characterized by lymphocytes and granulocytes infiltration, shortening and reduction of mucosal folds, decrease of enterocytes supranuclear vacuoles and thickening of the lamina propria (Uran et al., 2009; Kortner et al., 2012; Marjara et al., 2012; Sahlmann et al., 2013). Most of the adverse side effects of certain vegetable based diets on growth and health in fish, have been mostly, but not exclusively, ascribed to the action of specific anti-nutritional factors (ANFs) supplied by certain plant-protein rich derivatives. Such adverse effects were not always prevented or reversed with diets including highly purified vegetable protein derivatives or by supplementation with additives known to be beneficial in terms of gut health and immunity (Torrecillas et al., 2012; Gu et al., 2017; Mirghaed et al., 2019). Hence seeking for new or underexploited feed protein sources to replace or complement conventional ones in farmed fish diet is considered a suitable way to reduce and/or mitigate possible adverse effects of certain high vegetable diets on growth and health of some fish species (Aragao et al., 2020).

In this direction, the use of Processed Animal Proteins (PAPs) in the diet of carnivorous fish species has recently received renewed attention (Gasco et al., 2018; Galkanda-Arachchige et al., 2019; Nogales-Mérida et al., 2018).

Among PAPs, poultry by-product meal (PBM) is of great interest for aquafeed formulation as a cost-effective and widely available ingredient, very rich in protein with a nearly optimal essential amino acid profile (Cruz-Suárez et al., 2007; Gunben et al., 2014). PBM is also a proper source of

minerals and does not contain anti-nutritional factors. PBM has been successfully used to replace variable proportions of fish meals in the diet of a number of fish species (see review of Galkanda-Arachchige et al., 2019). In salmonids, diets high in PBM were shown to ensure optimal growth performance or perform similarly to those containing either fish meal and/or vegetable protein-rich derivatives as major dietary protein sources (Burr et al., 2013; Hatlen et al., 2015; Barreto-Curiel et al., 2016; Doughty et al., 2019).

Recently, in the light of a circular economy concept applied to aquaculture, much research has been addressed to the use of insect meals as novel protein sources in aquafeeds (Nogales-Mérida, et al., 2018). Besides low ecological footprint (Van Zanten et al., 2014; Smetana et al., 2019; Zarantoniello et al., 2020; Maiolo et al., 2020), medium/high protein levels and minor deficiency in essential amino acids, certain insect meals have been shown to contain biologically active compounds, like chitin, antimicrobial peptides and short-medium fatty acids (FAs) (Nogales-Merida et al., 2018), which have been associated to improved fish innate immune response (promoting immunomodulatory effects) and modulation of gut microbiome composition (Bruni et al., 2018; Rimoldi et al., 2019; Terova et al., 2019; Osimani et al., 2019; Zarantoniello et al., 2020). Chitin and its oligomers in particular, have been shown to possess antimicrobial and bacteriostatic properties against several harmful Gram-negative bacteria (Benhabiles et al., 2012; Nawaz et al., 2018; Zhou et al., 2013; Qin et al., 2014), while some short-medium-chain FAs, such as lauric acid (C12), are known to exert anti-inflammatory properties at intestinal level and antimicrobial activity on Gram-positive bacteria (Skrivanova et al. 2005, 2006; Spranghers et al., 2018; Vargas et al., 2018 ).

It should be noted that most available information on fish responses to diets including PBM and insect meal arises from studies where they were tested as single major substitutes for fish meal (Zarantoniello et al., 2018; Galkanda-Arachchige et al., 2019; Cardinaletti et al., 2019; Bruni et al., 2020). On the contrary, their possible roles as combined protein sources and functional feeds in plant and/or SBM protein-rich diets have been poorly investigated to date. Even though the partial replacement of dietary fish meal with a mixture of PBM and insect meal has already been tested with success in barramundi (Chaklader et al., 2019), the use of a combination of the two PAPs in diets, still needs to be investigated in other carnivorous fish species.

On these basis, the aim of the present study, which is part of a larger one, was to evaluate growth performances, liver and gut histology and macromolecular composition by spectroscopic tools and gut inflammatory response of rainbow trout (*Oncorhynchus mykiss*) fed diets deprived of fish

meal, where graded levels of a vegetable protein-rich ingredients (Vp) including SBM were replaced by defatted *Hermetia illucens* pupae meal (HM) or PBM, singly or in combination.

## 2. Material and methods

### 2.1. Ethics

The feeding trial experiment and all procedures involving animals were carried out in strict accordance with EU legal frameworks relating to the protection of animals used for scientific purposes (Directive 2010/63/EU). It was approved by the Ethics Committee of the Edmund Mach Foundation (n°99F6E.0) and the protocol was authorized by the Italian Ministry of Health (530/2018-PR).

### 2.2. Test diets

Eight diets were formulated to be grossly iso-proteic (45 % on DM), iso-lipidic (26% on DM) and iso-energetic (23.5 MJ/kg DM). The ingredient composition and proximate analysis of the test diets are shown in Table 1. A diet rich in vegetable protein derivatives (Vp) high in soybean meal (CV) was prepared in order to have a 10:90 fish to vegetable protein and 20:80 fish to vegetable lipid ratios, calculated by considering the crude protein and lipid contribution to the diet of all fish and vegetable-based dietary ingredients. In addition, a fish meal-based reference diet (CF) was formulated in order to have an opposite ratio between fish and vegetable protein and lipid sources (90:10 and 80:20; respectively). Five diets, coined *H10*, *H30*, *H60*, *P30*, and *P60*, were prepared by replacing graded levels (10, 30 and 60%) of crude protein from the vegetable protein-rich ingredients of the CV diet, by crude protein from a defatted *Hermetia illucens* pupae meal (HM; ProteinX™, from Protix, Dongen, The Netherlands) or poultry by-product meal (P; ECB Company S.r.l., Treviglio (BG), Italy) while maintaining a same 80:20 vegetable to fish lipid ratio as in the CV diet.

The set of the test diets comprised also another one named *H10P50*, where 60% of crude protein from the vegetable protein-rich ingredients (Vp) of the CV diet, was replaced by 10 and 50% protein from insect and poultry by-product meal respectively keeping constant to 20:80 the ratios fish/vegetable lipid sources as in the other test diets. Where necessary, diets were supplemented with essential amino acid to meet the nutrient requirement of rainbow trout (NRC, 2011). All diets were manufactured at SPAROS Lda. (Portugal) by extrusion in two pellet size (3 and 5 mm) and stored at room temperature, in a cool and aerated room. The test diets were analysed for dry

168 matter, crude protein and ash contents according to AOAC (1998). Total lipid content was  
 169 determined according to Folch et al. (1957). Gross energy content was measured by an adiabatic  
 170 bomb calorimeter (IKA C7000, Werke GmbH and Co., Staufen, Germany). The amino acids analyses  
 171 of the test diets were performed as described by Tibaldi et al. (2015). Acid hydrolysis with HCl 6  
 172 M at 115–120°C for 22–24 h was used for all amino acids except cysteine (Cys) and methionine  
 173 (Met), for which performic acid oxidation preceded acid hydrolysis and tryptophan that was  
 174 determined after lithium hydroxide (4M) hydrolysis.

191

### 192 2.3. Fish rearing system and growth trial

193 The study used 1,200 female rainbow trout (*Oncorhynchus mykiss*) selected from a batch of 3,000  
194 fish hatched at the fish farming facilities of the Edmund Mach Institute (San Michele all'Adige, TN,  
195 Italy). Fish with an average initial weight of 54.2±1.45 g, were randomly allotted into 24 groups of  
196 50 trout each assigned to 1600 L fiberglass tanks supplied with well water (Temperature, 13.3  
197 ±0.03°C; DO, 7.4±0.5mg/l) by a flow-through system ensuring a total water volume  
198 replacement/tank/h. After stocking, fish group were fed a commercial diet and adapted over two  
199 weeks to the experimental conditions. After this period fish group were assigned in triplicate to  
200 the test diets according to a completely random design. Fish were fed the test diet by hand twice a  
201 day, 6 days a week, at apparent visual satiety over 91 days. Uneaten feed pellets were recovered  
202 at the end of each meal and weighed after being dried in a oven. At the end of the growth trial,  
203 after a 24 h fasting period, the final biomass was recorded, and feed intake (FI, g/fish/day), specific  
204 growth rate (SGR,  $100 \times [(\ln \text{FBW} - \ln \text{IBW}) / \text{days}]$ ) and feed conversion ratio (FCR, feed  
205 intake/biomass gain) were calculated for each tank. Three fish per tank (9 per dietary treatment)  
206 were euthanized (300mg L<sup>-1</sup> MS-222; Finquel®, Argent Laboratories, Redmont-VI, USA) and  
207 samples of liver and distal intestine were carefully dissected and properly stored for histological,  
208 spectroscopic (FTIRI) and molecular analysis as described below.

209

### 210 2.4. Histology, morphometric analysis and histological indexes

211 Samples were prepared according to Cardinaletti et al., 2019. Briefly, after dissection, samples  
212 (n=9 for each dietary group) from distal intestine and liver were fixed by immersion in Bouin's  
213 solution and stored at 4°C for 24 h. Subsequently, samples were washed three times with 70%  
214 ethanol for 10 min and finally preserved in 70% ethanol solution. After dehydration by graded  
215 ethanol solutions, samples were washed with xylene (Bio-Optica, Milan, Italy) and embedded in  
216 solid paraffin (Bio-Optica, Milan, Italy). Paraffin blocks were cut with a microtome (Leica  
217 RM2125RTS, GmbH, Wetzlar, Germany) and 5-µm sections were stained with Mayer  
218 haematoxylin and eosin Y (H&E, Sigma-Aldrich, Milan, Italy). Stained sections were examined  
219 under a Zeiss Axio Imager.A2 (Zeiss, Oberkochen, Germany) microscope and the images were  
220 acquired by mean of a combined colour digital camera AxioCam 503 (Zeiss, Oberkochen,  
221 Germany).

222 The semi-quantitative evaluation of distal intestine morphology and histopathological indexes  
223 score assignment were performed based on mucosal folds height, mucosal folds fusion, lamina  
224 propria width, sub mucosa width and goblet cells abundance as previously described in Uran et al.,  
225 2009.

226 Specifically, for the morphometric evaluation of folds height ten transversal sections of distal  
227 intestine, at 200 µm intervals, for each sample, were analysed as described in Cardinaletti et al.,  
228 2019. All the undamaged and non-oblique folds (at least 150 measurements per fish) were  
229 measured using ZEN 2.3 software (Carl Zeiss Microscopy GmbH), and the measurements were  
230 reported as means of the folds height (µm) ±SD. Regarding the semi-quantitative analysis of  
231 histopathological indexes of enteritis, 3 whole intestine circular transversal sections for each fish,  
232 at 200 µm intervals, were analysed. For the histopathological indexes score, an arbitrary unit was  
233 assigned for each parameter as described in Panettieri et al. (2020).

234 The sections were analysed by experienced personnel in two independent blinded evaluations and  
235 the score assignment criteria are described in Tab.3.

236 In order to evaluate the percentage of fat fraction (PFF) in the liver, three sections of liver for each  
237 fish for each experimental group (n=9), at 100 µm intervals, were acquired and analysed by mean  
238 of the ImageJ software, setting an homogeneous threshold value according to Zarantoniello et al.,  
239 2019. Not evaluable areas on the sections, such as blood vessels and bile ducts, were not  
240 considered. Results were reported as the mean ±SD of the area occupied by fat on the total  
241 hepatic parenchyma analysed on the section.

242

	Score	Description
MF f	+	0-5 observation per section
	++	5-15 observation per section
	+++	>15 observation per section
LP w	+	2-5 $\mu\text{m}$
	++	5-15 $\mu\text{m}$
	+++	>15 $\mu\text{m}$
SM w	+	10-15 $\mu\text{m}$
	++	15-30 $\mu\text{m}$
	+++	>30 $\mu\text{m}$
GC	+	Scattered cells
	++	Diffused and widely spread
	+++	Highly abundant and tightly-packed cells

**Table 2.** Histological scoring system for the different parameters used as histopathological indexes of enteritis in the distal intestine. MF f: mucosal folds fusion; LP w: lamina propria width; SM w: submucosa width; GC: goblet cells relative abundance.

## 2.5. Fourier Transform Infrared Imaging Spectroscopy (FTIRI) measurements and data analysis

Samples preparation and FTIRI measurements were performed according to literature (Giorgini et al., 2015, 2018; Notarstefano et al., 2019, 2020). Briefly, samples (n=9 for each dietary group) from distal intestine and liver were collected and stored at -80°C. Samples were cut by using a cryotome; for each sample, three sections (10  $\mu\text{m}$  thick) were cut at 200  $\mu\text{m}$  away from each other. Sections were immediately deposited without any fixation process onto CaF<sub>2</sub> optical windows (1 mm thick, 13 mm diameter), and then let air-dry for 30 min.

FTIRI measurements were carried out by means of a Bruker Invenio interferometer, coupled with a Hyperion 3000 Vis-IR microscope and equipped with a Focal Plane Array (FPA) detector operating at liquid nitrogen temperature (Bruker Optics, Ettlingen, Germany). On each section, by means of a 15X condenser/objective, specific areas were detected, on which the IR maps were acquired in transmission mode in the MIR range (4000-800  $\text{cm}^{-1}$ ; spectral resolution 4  $\text{cm}^{-1}$ ; 128 scans). Before each acquisition, the background spectrum was acquired on a clean portion of the CaF<sub>2</sub> optical window. Raw IR maps were preprocessed by using the Atmospheric Compensation (to correct for the atmospheric contributions of carbon dioxide and water vapor), and Vector Normalization (applied on the full frequency range, to avoid any artifacts due to section thickness variations) routines (OPUS 7.5 software package).

*Distal intestine.* IR maps were acquired on intestinal folds; each map was 164x328  $\mu\text{m}$  in size and was composed by 8192 pixel/spectra with a spatial resolution 2.56x2.56  $\mu\text{m}$ .

False color images, showing the topographical distribution of the most relevant biological compounds inside the mapped areas, were created by integrating preprocessed IR maps under the following spectral regions: 3050-2800  $\text{cm}^{-1}$  (representative of lipids, Lipids); 1700-1480  $\text{cm}^{-1}$  (representative of proteins, Proteins), and 1112-980  $\text{cm}^{-1}$  (representative of mucin, Mucin).

To evaluate the biochemical composition of absorbent mucosa (the more external layer on intestinal folds), on this compartment, 200 spectra were extracted from each IR map. For all the experimental groups, the following band area ratios were calculated in relation to the total biological mass (TBM) analyzed: LIP/TBM (ratio between the area of the 3050-2800  $\text{cm}^{-1}$  region, representative of total lipids, and TBM, calculated by the sum of the integrated areas 3050-2800  $\text{cm}^{-1}$  and 1780-900  $\text{cm}^{-1}$ ); PRT/TBM (ratio between the area of the 1700-1480  $\text{cm}^{-1}$  region, representative of total proteins, and TBM, calculated as above described), and MUC/TBM (ratio between the area of the 1112-980  $\text{cm}^{-1}$  region, representative of mucin, and TBM, calculated as above described) (Integration routine, Mode B, OPUS 7.1 software package).

*Liver.* Due to the homogeneity of this tissue, 164x164  $\mu\text{m}$  size IR maps were acquired on different areas of each section (4096 pixel/spectra with a spatial resolution 2.56x2.56  $\mu\text{m}$ ).

False color images were created by integrating preprocessed IR maps under the following spectral regions: 3050-2800  $\text{cm}^{-1}$  (representative of lipids, Lipids); 1780-1700  $\text{cm}^{-1}$  (representative of fatty acids, Fatty Acids); 1700-1480  $\text{cm}^{-1}$  (representative of proteins, Proteins), and 1080-1000  $\text{cm}^{-1}$  (representative of glycogen, Glycogen).

For all the experimental groups, the following band area ratios were calculated and statistically analyzed: LIP/TBM (ratio between the area of the 3050-2800  $\text{cm}^{-1}$  region, representative of total lipids, and TBM, calculated as above described); FA/TBM (ratio between the area of the 1780-1700  $\text{cm}^{-1}$  region, representative of fatty acids, and TBM, calculated as above described); PRT/TBM (ratio between the area of the 1700-1480  $\text{cm}^{-1}$  region, representative of total proteins, and TBM, calculated as above described), and GLY/TBM (ratio between the area of the 1080-1000  $\text{cm}^{-1}$  region, representative of glycogen, and TBM, calculated as above described).

## **2.6. RNA extraction and cDNA synthesis**

Samples were prepared according to Piccinetti et al., 2014. Briefly, total RNA was extracted from distal intestine samples (n=9 for each experimental group, approximately 90 mg per sample) using RNAzol® RT reagent (Sigma-Aldrich®, R4533, Milan, Italy) and following the manufacturer's instructions. RNA concentration and integrity were analysed using NanoPhotometer® P-Class

(Implen, Munich, Germany) and Gel Red™ staining of 28S and 18S ribosomal RNA bands on 1% agarose gel, respectively. After extraction, complementary DNA (cDNA) was synthesised from 3µg of total RNA with the High Capacity cDNA Reverse Transcription Kit (Bio-Rad, Milan, Italy), following the manufacturer's instructions, diluted 1:10 in RNase-DNase free water and stored at -20°C until quantitative real-time PCR (qPCR). An aliquot of cDNA was used to check primer pair specificity.

306

## 2.7. Real-Time qPCR

The mRNA levels of selected genes, namely, interleukin-1β (*il1b*), interleukin-10 (*il10*), tumor necrosis factor alpha (*tnfa*), nuclear factor kappa-light-chain-enhancer of activated B cells (*nfkb*), myeloid differentiation primary response 88 (*myd88*) and toll-like receptor 1 (*tlr1*) were assessed. The primers sequences were retrieved from NCBI (<http://www.ncbi.nlm.nih.gov/>) and are summarised in Tab.4. Amplification products were sequenced, and homology was verified. Negative controls revealed no amplification products and no primer-dimer formation in control templates.

PCRs were performed according to Olivotto et al., 2011 in an iQ5 iCycler thermal cycler (Bio-Rad, CA, USA) and each sample was analysed via RT-qPCR in triplicate. Reactions were set on a 96-well plate by mixing, for each sample, 1µL cDNA diluted 1:20, 5µL of 2×concentrated iQ™ Sybr Green (Bio-Rad, CA, USA) as the fluorescent intercalating agent, 0.3µM forward primer, and 0.3µM reverse primer. The thermal profile for all reactions was 3 min at 95°C, followed by 45 cycles of 20 s at 95°C, 20 s at 60°C, and 20 s at 72°C. Fluorescent signal were detected at the end of each cycle and the melting curve analysis was performed to confirm that only one PCR product was present in these reactions.

For the relative quantification of the expression of genes involved in inflammation, *β-actin* and *60S* ribosomal RNA were used as housekeeping genes to standardize the results. Data were analysed using the iQ5 optical system software version 2.0, including Genex Macro iQ5 Conversion and Genex Macro iQ5 files (all from Bio-Rad). Modification of gene expression was reported with respect to all the groups. Primers were used at a final concentration of 10 pmol µL<sup>-1</sup>.

## 2.8. Statistical analysis

Growth performance data are expressed as means  $\pm$  standard error of the means (esm). Data were checked for normal distribution and homogeneity of variances before analysis, and growth parameters were subjected to one-way analysis of variance (ANOVA). When significant differences were detected, the Tukey's multiple-comparison test was used to assess differences among groups. Differences were considered significant when  $p < 0.05$ . Analyses were carried out using the SPSS-PC release 17.0 (SPSS Inc., Chicago, IL, USA). Data obtained from morphometric histological analysis, FTIR and RT-qPCR were analysed by one-way ANOVA, with diet as the explanatory variable. All ANOVA tests were followed by Tukey's post-hoc tests. The statistical software package Prism5 (GraphPad Software) was used. Significance was set at  $p < 0.05$  and all results are presented as mean  $\pm$  SD.

## 3. RESULTS

### 3.1. Growth performance

Fish promptly accepted all the diets and no mortality occurred throughout the trial. Fish growth performance after 91 days feeding is shown in table 4.

Fish fed diet *H10P50* resulted in significantly higher final body weight, SGR and lower FCR ( $p < 0.05$ ) when compared to those given *CV* and *CF* diets which did not differ from each other ( $p > 0.05$ ). Diets including medium or high levels of HM and PBM resulted in similar intermediate values between those observed for diets *CV* or *CF* and *H10P50* but did not differ from the latter in terms of FCR. The observed differences in SGR or FCR were barely but significantly affected by parallel changes in feed consumption. In fact, feed intake, was similarly increased ( $p < 0.05$ ) with all diets including the test ingredients as compared to diets *CV* and *CF* with this latter resulting in the lowest value ( $p < 0.05$ ).

Dietary treatment	Initial weight (g/fish)	Final weight (g/fish)	SGR	FI (g/fish/d)	FCR
<i>CV</i>	54.4	227.9 <sup>b</sup>	1.57 <sup>d</sup>	1.55 <sup>b</sup>	0.80 <sup>a</sup>
<i>CF</i>	53.6	231.2 <sup>b</sup>	1.61 <sup>cd</sup>	1.53 <sup>c</sup>	0.78 <sup>abc</sup>
<i>H10</i>	54.6	235.0 <sup>ab</sup>	1.63 <sup>bc</sup>	1.59 <sup>a</sup>	0.79 <sup>ab</sup>
<i>H30</i>	54.2	239.1 <sup>ab</sup>	1.63 <sup>bc</sup>	1.57 <sup>a</sup>	0.76 <sup>bcd</sup>
<i>H60</i>	54.7	241.0 <sup>ab</sup>	1.63 <sup>bc</sup>	1.57 <sup>a</sup>	0.76 <sup>bcd</sup>
<i>P30</i>	54.0	240.0 <sup>ab</sup>	1.64 <sup>abc</sup>	1.58 <sup>a</sup>	0.76 <sup>bcd</sup>
<i>P60</i>	53.8	244.0 <sup>ab</sup>	1.66 <sup>ab</sup>	1.59 <sup>a</sup>	0.75 <sup>cd</sup>
<i>H10P50</i>	54.7	254.8 <sup>a</sup>	1.69 <sup>a</sup>	1.63 <sup>a</sup>	0.73 <sup>d</sup>
<i>pooled standard error</i>	0.27	1.92	0.007	0.044	0.004

**Table 4.** Growth performance, specific growth rate (SGR), feed intake (FI) and feed conversion ratio (FCR) of rainbow trout fed the test diets over 91 days. Within each column, means with different superscript letters are significantly different ( $p < 0.05$ ).

### 3.2. Intestine histology

Histological analysis was performed in order to evaluate possible inflammation in distal intestine of trout fed the experimental diets.

A normal morphology of intestine histological structure was observed in fish fed diets *CF*, *P30*, *P60* and *H10P50* with finger-like mucosal folds (Fig.1 c,d) with aligned enterocytes forming the absorbent portion of the intestinal mucosa and scattered goblet cells, (Fig.1 a,b). Enterocytes were characterized by a nucleus at the base of the cell and an eosinophilic cytoplasm rich in supra-nuclear vacuoles (Fig. 1b); lamina propria was generally characterized by a low degree of cellularity, diffused lymphocytes and a mean thickness ranging from 2 to 5  $\mu\text{m}$  (Fig. 1a). Submucosa was about 10-15  $\mu\text{m}$  in thickness and was characterized by a connective layer with a low degree of cellularity (Fig 1a).

In fish fed diets *H30* and *H60*, a general increase in goblet cells abundance was observed. This was particularly evident in specimens of diet *H60*, which did not show obvious signs of inflammation, and displayed a remarkable increase in the goblet cells number, tightly-packed along the mucosal folds (Fig 1e).

Conversely, the distal intestine histology of fish fed diets *CV* and *H10* showed a high incidence of inflammatory signs, similar to those typically observed in soybean meal induced enteritis (SBMIE) in salmonids (Krogdahl et al., 2015). The most common inflammation signs were represented by a general atrophy of mucosal folds, a high presence of inflammatory cells influx and thickening of

387 the lamina propria and of the sub mucosa (Fig 1f). In these groups (CV and H10), oedema of the  
388 lamina propria and a high degree of mucosal folds fusion was also observed (Fig. 1g).  
389

390  
391  
392 **Figure 1. Histology of the distal intestine of trout fed the different experimental diets.** Example  
393 of distal intestine of trout fed diet CF showing a normal histological architecture, with regular  
394 lamina propria and submucosa thickness (a), scattered goblet cells (b) and aligned enterocytes  
395 with basal nucleus and abundant supra-nuclear vacuoles building the external layer of finger-like  
396 mucosal folds (c). H10P50 group distal intestine with no inflammation evidences (d). H60 group  
397 distal intestine showing abundant presence of goblet cells, tightly packed along the mucosal folds  
398 (e). CV group distal intestine showing an appreciable reduction of folds height with a high level of  
399 infiltrate (arrowhead) and thickening of lamina propria (f); distal intestine from H10 group showing  
400 mucosal folds fusion (circle) and oedema (OE) (g). LP: lamina propria; SM: submucosa; ECs:

enterocytes GC: goblet cell; n: nucleus; SV: supra-nuclear vacuoles; MF: mucosal fold. Scale: a,b=5µm; c,d,e,g=100 µm; f=10µm.

Mucosal folds height evaluations and the histopathological indexes score results are summarized in Tab.5. From the morphometric analysis of mucosal folds height, the highest values were observed in fish fed diet *CF* (1023±79 µm) showing significantly higher values ( $p<0.05$ ) compared to *CV*, *H10*, and *H10P50*, while no significant differences were observed with respect to *H30* and *H60* (907±51 µm and 1022±60 µm respectively). A significant ( $p<0.05$ ) shortening of mucosal folds was observed in fish given diet *CV* (620.5±17.4µm) and *H10* (671±44µm), with respect to all the other groups. Groups fed diets including PBM (*P30*, *P60*) and the mix of HM and PBM (*H10P50*) did not shown significant differences among them (833±76µm, 851±58µm and 827±88µm, respectively) with slight, even if significant, reduction of mucosal folds height compared fed *CF*, *H30* and *H60* diets ( $p<0.05$ ).

From the analysis of histopathological indexes (Tab.5), a high incidence of mucosal folds fusion and thickening of lamina propria and submucosa was observed in *CV* and *H10* groups compared to all the other groups. Low values of histopathological indexes score were observed in all the other experimental groups.

	MF (µm)	MF f	LP w	SM w	GC
<i>CV</i>	620±17 <sup>c</sup>	++/+++	+ / ++	+++	+
<i>CF</i>	1023±79 <sup>a</sup>	+	+	+	+
<i>H10</i>	671±44 <sup>c</sup>	++	+	++	+
<i>H30</i>	907±51 <sup>a</sup>	+	+	+	++
<i>H60</i>	1022±60 <sup>a</sup>	+	+	+	+++
<i>P30</i>	833±76 <sup>b</sup>	+	+	+	+
<i>P60</i>	851±58 <sup>b</sup>	+	+	+	+
<i>H10P50</i>	827±88 <sup>b</sup>	+	+	+	+

**Table 5.** Morphometric evaluation of mucosal folds and histopathological indexes score in distal intestine from fish fed test diets. MF: mucosal folds height; MF f: mucosal folds fusion; LP w: lamina propria width; SM w: submucosa width; GC: goblet cells abundance. MF height is expressed by the mean of the observation performed ±SD. In MF, different letters indicate significant differences ( $p<0.05$ ).

### 3.3. Histological evaluation of percentage of fat fraction (PFF) in liver

Liver histology showed a normal structure of liver parenchyma in all the experimental groups with the absence of appreciable inflammation signs (Fig.2). Liver from all experimental groups showed

high amount of fat accumulation, less appreciable in *CV* and *H10* groups (Fig 2a, b), which showed a more compact parenchyma with a lesser extent of lipid accumulation. PFF results are summarized in Tab.6 and showed significantly lower values in *CV* and *H10* groups liver compared to all the other experimental groups ( $p<0.05$ ).

**Figure 2. Liver histology.** Representative histological sections of liver from trout fed the different test diets. Scale bar=100µm.

	PFF (%)
<i>CV</i>	29.0±0.7 <sup>a</sup>
<i>CF</i>	45.9±5.4 <sup>b</sup>
<i>H10</i>	33.3±4.4 <sup>a</sup>
<i>H30</i>	37.0±3.3 <sup>b</sup>
<i>H60</i>	40.4±3.6 <sup>b</sup>
<i>P30</i>	35.0±2.4 <sup>b</sup>
<i>P60</i>	46.1±0.2 <sup>b</sup>
<i>H10P50</i>	36.9±3.3 <sup>b</sup>

**Table 6.** Percentage of fat fraction (PFF) in liver of trout fed the test diets (ImageJ software analysis). Data are reported as mean ±SD. Different letters indicate significant differences among the test diets ( $p<0.05$ ).

### 3.4. FTIRI analysis

*Distal intestine.* Fourier Transform Infrared Imaging spectroscopy (FTIRI) has been adopted as a new methodology to characterize the macromolecular composition of the intestinal mucosa. It

447 provided interesting information on the composition of the intestinal mucosal of the different  
448 experimental groups and showed as the nutrients transport in the intestine varied in relation of  
449 the experimental diets.

450 The topographical distribution of lipids, proteins, and mucin at the level of intestinal folds was  
451 investigated, by creating representative false colour images. In Fig.3, the hyperspectral imaging  
452 analysis of the distal intestine of *CV*, *CF* and *H10P50* samples is reported, as an example. The  
453 investigated macromolecules (lipids, proteins and mucin) have been predominantly detected at  
454 the level of the most external layer of intestinal folds, in all the analysed groups. This layer  
455 represents the absorbent portion of the intestinal mucosa and, as reported in histological images  
456 (Fig. 1b), the mainly represented cell types in this portion are enterocytes, which are characterized  
457 by the presence of abundant supra-nuclear vacuoles. Enterocytes build a continuous layer whit  
458 intercalated which goblet cells, producing and secreting different types of mucopolysaccharides,  
459 generally referred as mucin.

460

461

462 **Figure 3.** Microphotographs and false colour images of representative sections of *CV*, *CF* and  
463 *H10P50* distal intestine samples showing the topographical distribution of lipids (*Lipids* images,  
464 scale 0-5), proteins (*Proteins* images, scale 0-20), and mucin (*Mucin* images, scale 0-5) on the  
465 mapped areas. IR maps are 164x328  $\mu\text{m}$  in size and are composed by 8192 pixel/spectra with a  
466 spatial resolution 2.56x2.56  $\mu\text{m}$ . Different colour scale was adopted: white/light pink indicate high  
467 absorbance values of IR radiation, whilst black/dark blue low ones.

468

469 To evaluate changes in the biochemical composition of the absorbent portion of intestinal mucosa  
 470 in relation with the different diets, the following band area ratios were analysed: LIP/TBM (relative  
 471 amount of lipids), PRT/TBM (relative amount of proteins), and MUC/TBM (relative amount of  
 472 mucin) (Fig.4). An increase in the lipid content was observed only in *CF* diet with respect to all the  
 473 other diets, including *CV* one (LIP/TBM ratio,  $p<0.05$ ). No changes were observed in the protein  
 474 and mucin content as regards all the tested diets ( $p>0.05$ ).  
 475

476

477 **Figure 4. Biochemical composition of intestine mucosa in relation with the different diets.**  
 478 Relative amount of lipids (LIP), proteins (PRT) and mucin (MUC) in relation to the total biological  
 479 mass (TBM) analyzed. Values are presented as mean  $\pm$  SD. Different letters indicate significant  
 480 differences among the experimental groups ( $p<0.05$ ); n.s. indicates that differences among the  
 481 means value are not significant ( $p>0.05$ ).  
 482

483 *Liver.* In Fig. 5, false colour images representing the topographical distribution of lipids, fatty acids,  
 484 proteins, and glycogen in *CV*, *CF* and *H10P50* in liver samples are showed. A general higher

485 presence and distribution of lipids, fatty acids and glycogen has been detected in all the analysed  
486 sections of *CF* and *H10P50* groups.  
487

488  
489 **Figure 5.** Microphotographs and false colour images of representative sections of *CV*, *CF* and  
490 *H10P50* liver samples showing the topographical distribution of lipids (Lipids images, scale 0-5),  
491 fatty acids (Fatty Acids images, scale 0-2), proteins (Proteins images, scale 0-20), and glycogen  
492 (Glycogen images, scale 0-10) on the mapped areas. IR maps are 164x164  $\mu\text{m}$  in size and are  
493 composed by 4096 pixel/spectra with a spatial resolution 2.56x2.56  $\mu\text{m}$ . Different colour scale was  
494 adopted: white/light pink indicate high absorbance values of IR radiation, whilst black/dark blue  
495 low ones.  
496  
497

498 In order to obtain semi-quantitative information on the biochemical composition of liver in  
 499 relation with the different diets, the following band area ratios were analyzed: LIP/TBM (relative  
 500 amount of lipids), FA/TBM (relative amount of fatty acids), PRT/TBM (relative amount of proteins)  
 501 and GLY/TBM (relative amount of glycogen) (Fig. 6). An increase in the lipid content was observed  
 502 in all the experimental groups with respect to CV one (LIP/TBM,  $p<0.05$ ). Statistically significant  
 503 higher values of fatty acids were found in CF, H30, H60 samples (FA/TBM,  $p<0.05$ ). Tiny but  
 504 statistically significant differences were detected in the protein content, with higher amounts in  
 505 H10, H30 and P60 samples and lower ones in CF and P30 (PRT/TBM,  $p<0.05$ ). As regards glycogen,  
 506 a significantly lower relative amount was observed in CV compared to the other groups ( $p<0.05$ ).  
 507 Values of GLY/TBM were significantly higher in all the other experimental groups, compared to CV,  
 508 even if lower if compared to CF group.

509  
 510 **Figure 6. Biochemical composition liver in relation with the different diets.** Relative amount of  
 511 lipids (LIP), fatty acids (FA), proteins (PRT) and glycogen (GLY) in relation to the total biological  
 512 mass (TBM) analyzed. Values are presented as mean  $\pm$  SD. Different letters indicate significant  
 513 differences among the experimental groups ( $p<0.05$ ); n.s. indicates that differences among the  
 514 means value are not significant ( $p>0.05$ ).

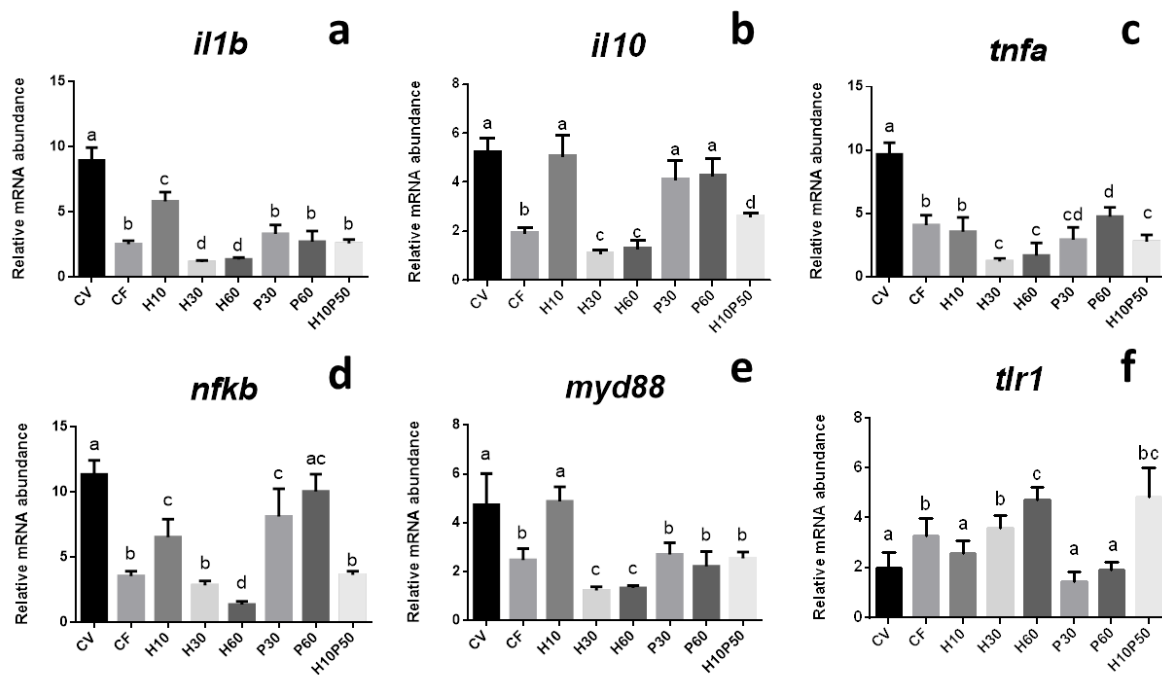

### 3.1. Gene expression

Relative mRNA abundance related to gene involved in inflammation was analysed in distal intestine of fish fed the experimental diets. Regarding *il1b* (Fig. 7a), a significantly higher gene expression was observed in CV compared to all other groups. H10 group showed significantly lower *il1b* gene expression compared to CV, but was a significantly upregulated respect to the other groups. H30 and H60 groups showed a significant *il1b* downregulation compared to all other dietary treatments, while no significant differences between the two groups (H30 and H60) were detected. *il10* gene expression of (Fig. 7b) resulted significantly higher in CV, H10 and P60 compared to other groups. On the contrary, H30 and H60 showed a significant downregulation of *il-10* gene expression with respect to the other dietary groups.

Results on *tnfa* (Fig. 7c) gene expression showed a significant higher expression in CV group compared to the other groups. No significant differences in *tnfa* gene expression were detected between CF and P60. Conversely, *tnfa* gene expression resulted significantly downregulated in H10, P30 and H10P50 with respect to CV and P60. H30 and H60 expression showed significantly lower values compared to the other dietary groups, except for H10P50.

Regarding *nfkb* (Fig. 7d), a significantly higher gene expression was observed in CV, P30 and P60 compared to the other dietary groups. Differently, a significant *nfkb* downregulation was shown in CF, H30 and H10P50 groups with respect to CV, P30 and P60.

Gene expression of *myd88* (Fig. 7e) was significantly higher in CV and H10 compared to the other dietary groups, while resulted significantly downregulated in CF P30, P60, H10P50 groups compared to CV and H10 ( $p < 0.05$ ). Similarly. to what observed for *il1b*, *il10* and *tnfa*, *myd88* expression was significantly downregulated in H30 and H60 groups compared to all the other groups, whit no significant differences between the two groups. Finally, as regards *tlr1* gene expression, significantly higher values were detected in H60 and H10P50 groups ( $p > 0.05$ ), followed by H30 and CF ( $p < 0.05$ ), compared to the other experimental groups (Fig. 7f).

**Figure 7. RT-qPCR.** Relative mRNA abundance of genes analysed. Values are presented as mean  $\pm$ SD. Different letters indicate significant differences among the experimental groups ( $p < 0.05$ ).

#### 4. Discussion

Vegetable protein-rich derivatives and some processed animal proteins such as PBM and more recently HM, have been the subject of a number of studies aimed to assess their feasibility in replacing FM in aquafeeds (Daniel, 2018; Galkanda-Arachchige et al., 2019; Nogales-Mérida et al., 2018). Changing the paradigm, for the first time in the present study, graded levels of PBM and/or HM were used to replace a blend of Vp (including substantial proportions of SBM) in practical diets for rainbow trout, totally deprived of FM. Since Vp and especially SBM are known to induce physio-pathological side-effects in Salmonids (Buttle et al., 2001; Romarheim et al. 2008), the main hypothesis of the present study was to verify a possible mitigation of these adverse effects through the substitution of dietary Vp rich in SBM with HM and PBM singly or combined.

The results obtained so far showed that, even at the highest dietary inclusion level, both HM and PBM, led to better growth performance and feed conversion ratios than those attained by fish given a vegetable protein-based diet (CV), and similar or slightly better, than those observed in fish fed a fish meal-based diet (CF).

564 As already consistently reported in salmonids, lower growth performance was expected in CV due  
565 to its high level of SBM (Collins et al, 2013). Growth response of rainbow trout in the present  
566 experiment are not easily comparable to other studies on salmonids, including trout. In fact, in  
567 previous studies, HM or PBM were mostly evaluated as FM substitutes in diets containing variable,  
568 but low levels, of vegetable proteins (Burr et al. 2012; Hatlen et al 2015; Renna et al., 2017) and  
569 different types and composition of HM were used (St-Hilaire et al., 2007; Cardinaletti et al., 2019).  
570 In the current study, also combining PBM and HM (*H10P50*) to replace 60% of dietary crude  
571 protein supplied by vegetable ingredients in a diet without fish meal, resulted in pretty high  
572 growth performance and feed conversion efficiency. Since all diets were actually designed to meet  
573 the rainbow trout nutrient requirements, improved growth performance and feed conversion  
574 efficiency observed here with diet H10P50 and with diets including moderate to high levels of HM  
575 and PBM could possibly result from a better overall digestible amino acid balance and/or  
576 improved gut health and nutrient digestibility when graded levels of plant proteins and SBM were  
577 replaced by the test ingredients. Contrary to our results, Dumas et al. (2018), in trout, reported  
578 significantly reduced growth and feed conversion efficiency in response to a total replacement of  
579 dietary fish meal protein for nearly equal proportions of crude protein supplied by defatted HM,  
580 PBM and a blend of vegetable ingredients. These opposite outcomes could partly depend on  
581 differences in the proportions of main alternate protein sources and the composition of the  
582 vegetable protein blend between experiments. However, this also suggests that different ratios  
583 among major alternative protein sources, and particularly the ratio between PBM and HM in the  
584 diet, could be a crucial aspect and needs to be optimized in further trials to allow optimal  
585 performance to be attained through diets deprived of fish meal. However, it should be noted that  
586 in the study of Dumas et al. (2018) fish growth was in general much higher than that attained in  
587 the present investigation, possibly due to a different and faster-growing trout strain, more  
588 intensive feeding schedule, higher stocking density and water temperature. This suggests that also  
589 other factors, interactively with the diet composition could be responsible of the divergent  
590 response between experiments.

591 In order to evaluate whether changes in fish growth response related to the major dietary protein  
592 sources were associated to changes in certain gut-health related functions, several physiological  
593 response parameters were analyzed at the end of the trial through a multidisciplinary approach,  
594 with major focus on the distal intestine. As expected, fish fed diets high in vegetable proteins and  
595 including SBM over 20% w:w (CV and *H10*) showed the typical histological changes observed in

the distal intestine of salmonids fed diets with medium to high levels of dietary SBM (Krogdahl et al. 2003; Krogdahl et al., 2010). On the contrary, all diets consisting of lower proportions of Vp (SBM equal or less than 16%), regardless of the level of PBM or HM used, did not display histopathological changes compared to the *CF* counterpart. A substantial increase in mucous cells in distal intestine of fish fed medium and high HM dietary inclusion levels (*H30* and *H60*) was observed. This finding is consistent with previous studies reporting that chitin present in HM is usually associated with greater digestive tract lubrication, necessary to preserve the integrity of the intestinal mucosa (Bansil, & Turner, 2006; Elia et al., 2018; Vargas et al., 2018; Cardinaletti et al., 2019).

The histological observations were also supported by the molecular approach, which represents a useful tool to provide early information on inflammation processes, even in absence of clear histopathological evidences (Seierstad et al., 2009; Sahlmann et al., 2013; Li et al., 2016). All the main inflammatory markers here analysed were upregulated in fish fed *CV* diet. This agrees with previous studies in which these markers were highly expressed in Atlantic salmon fed diets high in SBM (Uràn et al., 2008; Marijara et al, 2012). Similarly, and accordingly to the histological analysis, the molecular results confirmed that a low level of dietary HM (*H10*) was not able to mitigate the intestinal inflammatory response here observed in distal intestine. Conversely, when higher percentages of dietary Vp (including SBM) were replaced as in diets *H30*, *H60*, *P30*, *P60* and *H10P50*, a general downregulation of most of the analysed inflammatory markers was evident. This effect was stronger in fish fed *H30* and *H60* diets than in those fed PBM, resulting in a dose-dependent effect of HM dietary inclusion for some of the molecular markers analysed (*nfkB* and *tlr1*). The observed downregulation of inflammatory markers due to increased replacement of Vp with HM and/or PBM, seems primarily a consequence of a concurrent reduced SBM content in diets, possibly associated to a down-regulation of intestinal *tnfa* expression (Sealey et al., 2009). However, it is interesting to note that results obtained in the present study suggest a specific anti-inflammatory role of HM. *Hermetia illucens* pre-pupae, contain bioactive compounds including chitin, medium-short FAs (lauric acid in particular) and antimicrobial peptides (Gasco et al., 2018; Vogel et al., 2018), which have been shown to positively influence gut health (Henry et al., 2015; Osimani et al., 2019; Terova et al., 2019). Besides mitigating gut inflammatory events, HM has been suggested to possess immune-boosting properties in fish, specifically against bacterial diseases (Esteban et al., 2001; Cuesta et al., 2003; Ringø et al., 2012). The high *tlr1* gene

expression observed in both groups fed on *H30* and *H60* diets seems to confirm this property, being this receptor involved in bacterial infections resistance (Wei et al., 2011; Li et al., 2018).

Recently FTIR analyses has been successfully applied to characterize trout intestine (Giorgini et al., 2018) as well as a new technique to study its macromolecular building and absorptive functions in response to dietary changes (Cardinaletti et al. 2019; Zarantoniello et al., 2020). In this investigation the FTIR technique was applied to evaluate if varying major dietary protein sources affected the macromolecular composition of the distal intestine. Moreover, given the susceptibility of DI to enteritis in salmonids (Baeverfjord and Krogdahl, 1996; Penn et al., 2011; Krogdahl et al., 2015) we evaluated if and to what extent its macromolecular building could reflect impaired functions due to a different inflammatory status.

On this regard, as previous demonstrated by Giorgini et al. (2018), false colour images analysis allowed to appreciate the presence of lipids, proteins and mucin in the outer layer of mucosal folds, corresponding to the absorptive mucosa. Compared to fish fed diet *CF*, the reduced amount of total lipids detected by FTIRI in the distal intestine mucosa of fish fed all diets including variable proportions of Vp, may be related to the presence of SBM in the diet which is known to impair intestine nutrient and lipid absorption besides inducing enteritis (Kortner et al., 2014; De Santis et al., 2015). The relative lipid content of DI mucosa was less reduced in fish fed *H10P50*, and this may be related to a combined effect of a low dietary Vp (SBM) content in association to HM inclusion.

When testing new feed ingredients, besides the gastrointestinal tract, the liver represents another important target organ to investigate fish nutritional status and welfare (Balasubramanian et al., 2016; Gregory et al., 2016; Panserat et al., 2020). In this regard, both histology and FTIRI analyses revealed a reduced liver lipid accumulation in fish fed diet *CV* compared to all the other ones, confirming the well-known lipid lowering effect of dietary SBM in fish tissues (Olli et al., 1994; Romarheim et al., 2006, 2008; Yamamoto et al., 2007). Interestingly, FTIRI allowed to detect a higher amount of total liver FAs in fish fed medium and high levels of HM in the diet (*H30* and *H60*) compared to all the other treatments except *CF*. This result is supported by previous studies in which different fish species fed diets including HM showed hepatic FA accumulation (Vargas et al., 2018; Zarantoniello et al., 2020) and it can be mainly ascribable to the HM FAs profile, known to be rich in MUFA and SFA rather than PUFAs (Zarantoniello et al., 2019; Abd El-Hack et al., 2020; Bruni et al., 2020, Ravi et al., 2020).

658 A significantly reduced glycogen deposition was also observed in the liver of fish fed diet CV  
659 compared to all the other dietary treatments. This is in agreement with previous studies, showing  
660 a reduced glycogen accumulation in trout fed high SBM inclusion (Ostaszewska et al., 2015) and  
661 seems primarily related to a low starch intake due to the reduced level of starchy ingredients in  
662 the same diets (Table 2). In general, the FTIRI results were consistent in confirming that liver  
663 glycogen deposition in fish fed the different diets correlates with the starch content of the  
664 corresponding diets ( $r=0.88$ ;  $p<0.01$ ) as previously observed by Enes et al. (2011). This supports  
665 the reliability of FTIRI application to investigate the metabolic response of fish to dietary changes.

666

667 In conclusion, the present study showed that moderate to high dietary levels of defatted HM or  
668 PBM, to replace or complement vegetable protein-rich ingredients and SBM in diets deprived of  
669 fish meal, resulted in improved growth and gut health in rainbow trout. It is intriguing to note that,  
670 the combination of the two alternative ingredients resulted in high SGR and FCR. This warrants  
671 further investigation on fish body composition, to ascertain to what extent improved growth and  
672 feed efficiency resulted from improved protein retention as a possible consequence of a better  
673 overall digestible amino acid balance due to improved gut health and nutrient digestibility. In fact,  
674 the diet design of this experiment allowed to observe a beneficial anti-inflammatory role in distal  
675 intestine of moderate to high HM levels in diets rich in vegetable protein and SBM, which was  
676 greater than that observed with PBM alone and went beyond the concurrent declining levels of  
677 dietary SBM and Vp. Further studies need to be addressed to better explain this positive role of  
678 dietary HM in trout. Finally, the results obtained so far, provide support to a reliable use of novel  
679 protein and lipid sources in developing a new generation of sustainable and healthy fish diets that  
680 meet the circular economy principles.

## 1104 Captions

1106 **Figure 1.** Histology of the distal intestine of trout fed the different experimental diets. Example of  
1107 distal intestine of trout fed diet *CF* showing a normal histological architecture, with regular lamina  
1108 propria and submucosa thickness (a), scattered goblet cells (b) and aligned enterocytes with basal  
1109 nucleus and abundant supra-nuclear vacuoles building the external layer of finger-like mucosal  
1110 folds (c). *H10P50* group distal intestine with no inflammation evidences (d). *H60* group distal  
1111 intestine showing abundant presence of goblet cells, tightly packed along the mucosal folds (e). *CV*  
1112 group distal intestine showing an appreciable reduction of folds height with a high level of  
1113 infiltrate (arrowhead) and thickening of lamina propria (f); distal intestine from *H10* group showing  
1114 mucosal folds fusion (circle) and oedema (OE) (g). LP: lamina propria; SM: submucosa; ECs:  
1115 enterocytes GC: goblet cell; n: nucleus; SV: supra-nuclear vacuoles; MF: mucosal fold. Scale:  
1116 a,b=5µm; c,d,e,g=100 µm; f=10µm.

1117

1118 **Figure 2.** Liver histology. Representative histological sections of liver from trout fed the different  
 1119 test diets. Scale bar=100µm.

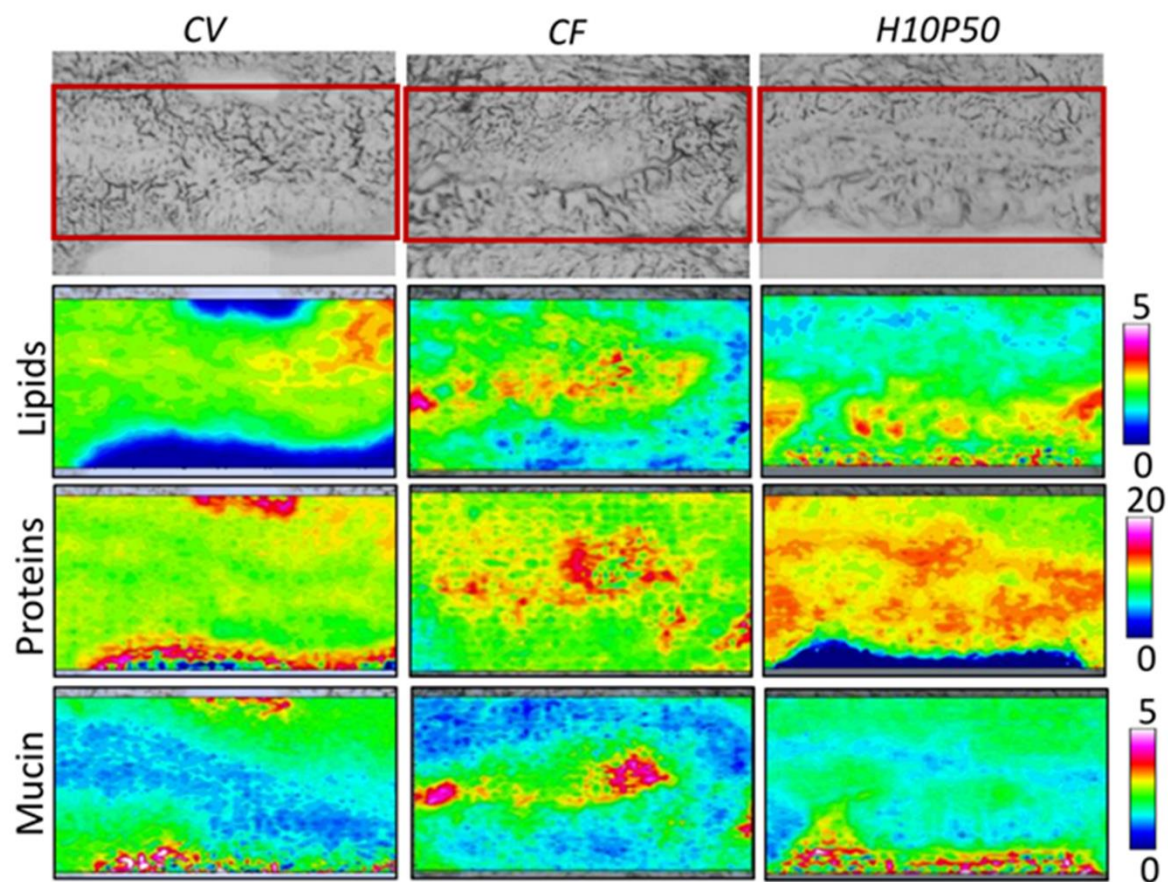

1120

1121 **Figure 3.** Microphotographs and false colour images of representative sections of *CV*, *CF* and  
 1122 *H10P50* distal intestine samples showing the topographical distribution of lipids (Lipids images,  
 1123 scale 0-5), proteins (Proteins images, scale 0-20), and mucin (Mucin images, scale 0-5) on the  
 1124 mapped areas. IR maps are 164x328  $\mu\text{m}$  in size and are composed by 8192 pixel/spectra with a  
 1125 spatial resolution 2.56x2.56  $\mu\text{m}$ . Different colour scale was adopted: white/light pink indicate high  
 1126 absorbance values of IR radiation, whilst black/dark blue low ones.

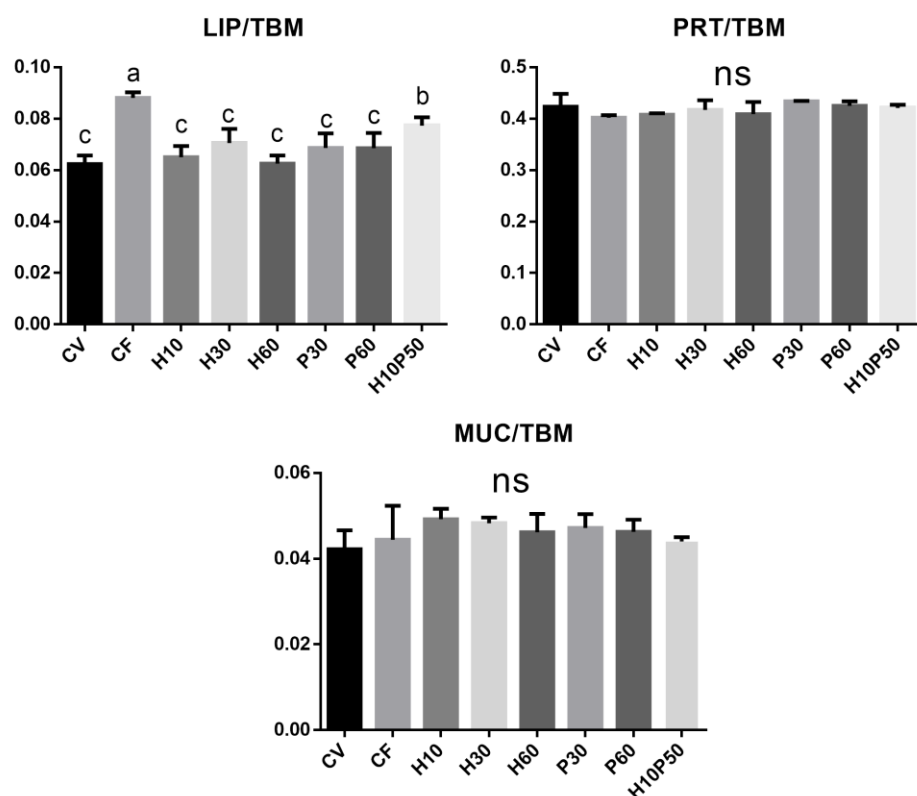

1127

1128

1129 **Figure 4.** Biochemical composition of intestine mucosa in relation with the different diets. Relative  
1130 amount of lipids (LIP), proteins (PRT) and mucin (MUC) in relation to the total biological mass  
1131 (TBM) analyzed. Values are presented as mean  $\pm$  SD. Different letters indicate significant  
1132 differences among the experimental groups ( $p < 0.05$ ); n.s. indicates that differences among the  
1133 means value are not significant ( $p > 0.05$ ).

1134

1135 **Figure 5.** Microphotographs and false colour images of representative sections of *CV*, *CF* and  
 1136 *H10P50* liver samples showing the topographical distribution of lipids (Lipids images, scale 0-5),  
 1137 fatty acids (Fatty Acids images, scale 0-2), proteins (Proteins images, scale 0-20), and glycogen  
 1138 (Glycogen images, scale 0-10) on the mapped areas. IR maps are 164x164  $\mu\text{m}$  in size and are  
 1139 composed by 4096 pixel/spectra with a spatial resolution 2.56x2.56  $\mu\text{m}$ . Different colour scale was  
 1140 adopted: white/light pink indicate high absorbance values of IR radiation, whilst black/dark blue  
 1141 low ones.

1142

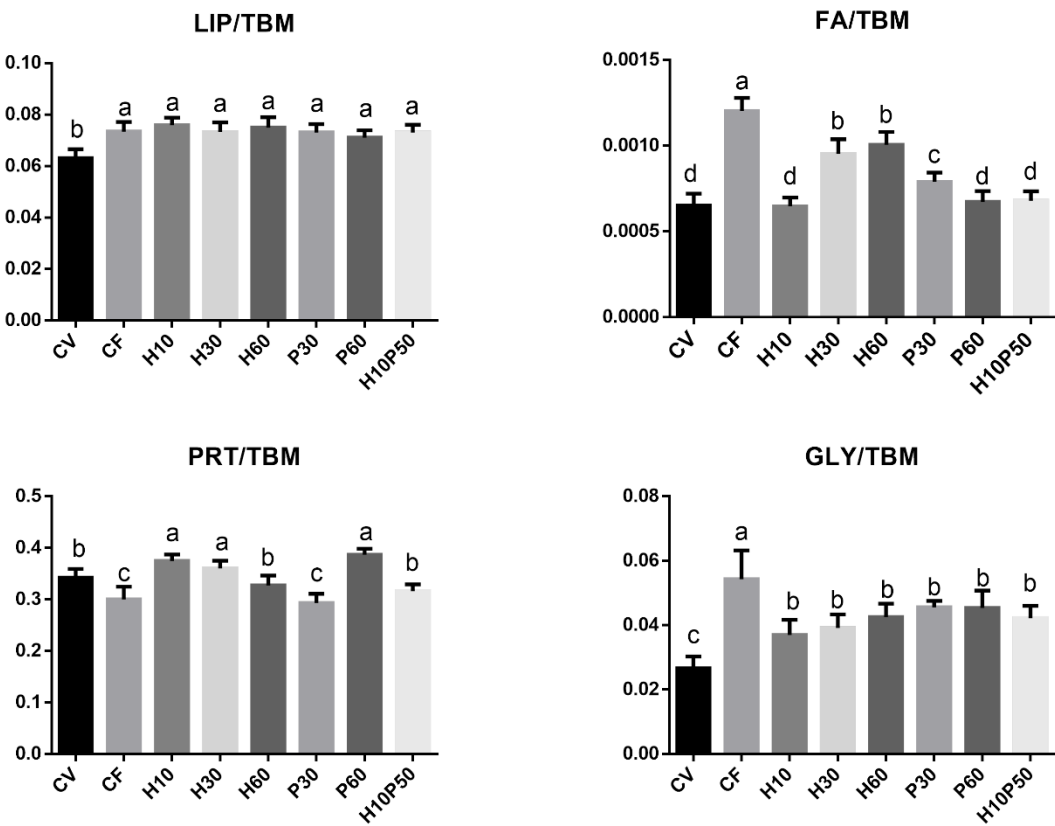

1143

1144

1145

**Figure 6. Biochemical composition liver in relation with the different diets.** Relative amount of lipids (LIP), fatty acids (FA), proteins (PRT) and glycogen (GLY) in relation to the total biological mass (TBM) analyzed. Values are presented as mean  $\pm$  SD. Different letters indicate significant

1146 differences among the experimental groups ( $p < 0.05$ ); n.s. indicates that differences among the  
 1147 means value are not significant ( $p > 0.05$ ).

1148  
 1149 **Figure 7. RT-qPCR.** Relative mRNA abundance of genes analysed. Values are presented as mean  
 1150  $\pm$ SD. Different letters indicate significant differences among the experimental groups ( $p < 0.05$ ).
