Title	Effects of BPA on zebrafish gonads: focus on the endocannabinoid system
Article type	Research Paper

Abstract

Bisphenol A (BPA), a monomer used for polycarbonate manufacture, has been widely reported as an endocrinedisrupting chemical (EDC). Among other alterations, BPA induces reproductive dysfunctionalities. Changes in the endocannabinoid system (ECS) has been recently shown to be associated with reproductive disorders. ECS is a lipidbased signaling system (cannabinoid receptors, endocannabinoids and enzymatic machinery) involved in several physiological functions. The main goal of the present study was to assess the effects of two environmental concentrations of BPA (10 and 20 µg/L) on the ECS in 1-year zebrafish gonads. In the males, BPA increased the gonadosomatic index (GSI) and altered testicular levels of endocannabinoids as well as reduced the testicular area occupied by spermatogonia. In the male liver, exposure to 20 µg/L BPA significantly increased vitellogenin (vtg) transcript levels. In female zebrafish, BPA altered ovarian endocannabinoid levels, elevated hepatic vtg mRNA levels as well as increased the percentage of vitellogenic oocytes in the ovaries. In conclusion, exposure to two environmentally relevant concentrations of BPA altered ECS and consequently, gonadal function in both male and female zebrafish.

UNIVERSITÀ Politecnica Delle Marche

Dipartimento di Scienze della Vita e dell'Ambiente **DISVA**

January 30th 2020

Dear Editor,

I enclose an original article entitled "**Effects of BPA on zebrafish gonads: focus on the endocannabinoid system**" co-authored by Isabel Forner-Piquer, Silvia Beato, Fabiana Piscitelli, Stefania Santangeli, Vincenzo di Marzo, Hamid R. Habibi, Francesca Maradonna and myself, Oliana Carnevali, for consideration as an article in Environmental Pollution.

In the present manuscript, we reported the results obtained after 21 days exposure to two different concentrations of Bisphenol A (BPA), 10 and 20 μ g/L (based on BPA environmental concentrations), on the endocannabinoid system in both ovary and testis. The endocannabinoid system was used as a novel target due to its role on reproductive physiology.

Thus, this study can be considered as continuum of the recent effort on investigating the effects of Bisphenol A. Indeed, our results reported that BPA induced alterations on the levels of endocannabinoids and transcriptomic changes in genes coding for the endocannainoid system and reproductive markers. In addition, the histological analyses on gonads evidenced alterations of gametogenesis in both ovary and testis.

Finally, we declare no conflict of interest associated with this publication, and we state that none of the material contained in the present manuscript has been published or is under consideration in any other place.

We believe that our findings will be of interest to the readers of your journal.

Thank you for considering this article and please, let us know if there is further information we can provide.

Sincerely,

Prof Oliana Carnevali CONTOC

Reviewer 4

Minor points:

1) GSI should be defined in the main text the first time it is used (not just the abstract).

GSI has been defined in line 106 (materials and methods) and 176 (results).

2) The authors are expressing their data in deltaCt in table 3 and 4 and figure 3, and this must be stated. Note that these are not 'arbitrary units' as indicated in the methods. The authors must explicitly state this and indicate where this is different from the fold change analysis 2^-ddCt. Therefore, I suggest that the legend for table 3 and 4 and figure 3 be changed from "Data are expressed as means \pm SEM" to "Data are expressed as mean dCt \pm SEM".

As the reviewer suggested, the image legends have been modified.

1 HIGHLIGHTS

- 2 1. BPA altered the endocannabinoid system in zebrafish gonads.
- 3 2. BPA (20 μ g/L) decreased the percentage of the area occupied by spermatogonia in the testis.
- 4 3. BPA (20 μ g/L) up-regulated the hepatic *vtg* expression in male and females.
- 5 4. BPA increased male GSI.

1. INTRODUCTION

57 Since 1940, BPA has been used for the manufacture of polycarbonate products and epoxy resins in 58 the plastic industry because of its capacity to increase heat resistance and elasticity [1]. Due to its 59 extensive use, BPA can be globally found in the aquatic environment and therefore, in humans and 60 wildlife [2]. BPA is known to enter the aquatic ecosystem by diffusion from wastewater treatment 61 plants and landfill sites [3]. Overall, BPA concentrations in the aquatic environment are variable, 62 depending on the location, reaching on average 21 µg/L in surface waters [4,5]. BPA can interact with 63 nuclear estrogen receptors (ER) alpha and its membrane-bound form (mER) [6,7], ER beta [8] and 64 the G protein-coupled receptor 30 (GPR30) [9]. Additionally, BPA exerts estrogenic activity at low 65 concentrations [10] and can interfere with androgen mediated pathways [11-14]. Consequently, BPA 66 has been linked with alterations in male and female reproduction and epigenetic markers [15–18], 67 gonadotrophic cell hypertrophy and hyperplasia [19], follicular atresia [20], transcriptomic profile of 68 genes coding for reproductive signals [15,19,21-23], sperm physiology and motility [21,24,25], 69 hormone levels [23,26,27], sexual differentiation [28], abnormal neuronal development [11], 70 morphological development [29], and metabolic dysfunction [30].

71

72 It is now well established that the ECS is involved in different reproductive processes [31-33]. The 73 ECS is a lipid signaling system based on lipid mediators, the endocannabinoids (Anandamide: AEA, 2-74 arachidonoylglycerol: 2-AG). It can be expanded to include endocannabinoid-like mediators such as 75 *N*-oleoyl ethanolamine (OEA) and *N*-palmityl ethanolamine (PEA). AEA and 2-AG exert their activity 76 through G protein-coupled receptors, i.e. the cannabinoid receptor type I (CB1 or CNR1) and type II 77 (CB2 or CNR2), as well as other molecular targets. The endocannabinoids are synthetized on demand, 78 mainly through the N-acyl phosphatidylethanolamine-specific phospholipase D (NAPE-PLD, for AEA) 79 and Diacylglycerol Lipase Alpha (DAGLa, for 2-AG), from membrane phospholipid precursors after 80 reuptake into the cytosol, facilitated by intracellular degrading enzymes such as fatty acid amide 81 hydrolase (FAAH) and monoglyceride lipase (MGLL). NAPE-PLD and FAAH also regulate OEA and PEA 82 tissue concentrations.

In humans, higher levels of AEA impaired sperm viability and motility [34], and in mice, lower levels of 2-AG promoted epididymal sperm cell start-up [35]. Inactivation of CB1 caused ineffective histone displacement, reduced chromatin condensation and DNA damage in mouse sperm [36]. In females, a correct tone of AEA was reported to be necessary during human oocyte maturation [37,38]; however, higher levels of AEA may also decrease the levels of progesterone, which is associated with implantation failure and/or abnormal development of the mammalian fetus [39]. Indeed, a crosslink
between endocannabinoids and sex steroids is reported elsewhere [40].

Finally, recent studies demonstrated the ability of BPA to deregulate the ECS in different species
[22,26,41-43]. Thus, we here examined the adverse effects of BPA on the gonadal ECS in adult
zebrafish, following 21-day exposure to two different environmental concentrations (10 and 20 μg
BPA/L).

94

96

95 2. MATERIALS AND METHODS

2.1. BPA treatment

97 BPA exposure was conducted in one-year zebrafish (AB strain) following previous publications 98 [4,5,15,22,44]. Two nominal concentrations of BPA were tested: 10 and 20 µg/L. Absolute ethanol 99 (100% EtOH) was used as a solvent carrier with a final concentration of 10 μ L EtOH / L water (0.001%) 100 v/v), which was well below the activity threshold (Hutchinson et al., 2006). After three weeks, fish 101 were euthanized with MS-222 (3-aminobenzoic acid ethyl ester) (Sigma-Aldrich) according to 102 University of Calgary Animal Care protocol (AC15-0183). Ovaries and testes were immediately frozen 103 in dry ice and stored at -80 °C until use for subsequent RNA extraction and endocannabinoid assays. 104 For histological procedures, the gonads were fixed in Bouin solution overnight, washed and stored 105 within EtOH 70%.

106 Gonadosomaic Index (GSI) was calculated: [(gonad weight/ total zebrafish weight) * 100]

107

108 **2.2 Quantitative real-time PCR (RT-qPCR).**

109 RNA was extracted from the gonads after gently homogenisation with TRIzol reagent (Invitrogen), 110 followed by chloroform disaggregation into a light aqueous layer in the upper part containing RNAs 111 and a lower one with proteins and DNAs. Then, the upper layer was transferred to a new Eppendorf 112 and the RNA was precipitated with isopropanol and washed twice with absolute ethanol. Finally, the 113 samples were treated with DNAse following [15]. Quantification of the RNA was determined by 114 spectrophotometry using a Nanophotomether TM P-Class (Implen). Quality of the mRNA (integrity, 115 presence of genomic-DNA) was assessed by electrophoresis in 1% agarose gel.

116 Reverse transcription was conducted from 1 μ g mRNA with High-Capacity cDNA Reverse 117 Transcription Kit (Applied Biosystems) following the manufacturer guidelines. The cDNA obtained 118 with the retrotranscription (MyCycler Thermal Cycler System, Bio-Rad) was considered as the stock (1:1), this stock was diluted with miliQ water (1:10) to obtain the working concentrations. All the
cDNAs were kept at - 20 °C.

121 For the RT-qPCRs, SYBR Green method was used with an iQ5 multicolor Real-Time PCR detection 122 system (Bio-Rad) with single transparent strips. All replicates (n = 5) were run in duplicate. For each 123 reaction, the mix contained: 1 μ L of cNDA (1:10) + 5 μ L iQ SYBR Green Supermix (Bio-Rad) + 3.8 μ L 124 miliQ water + 0.1 µL forward primer + 0.1 µL reverse primer. Final concentration of primers was 10 125 pmol/µL. The thermal cycling was as follow: 95 °C for 3 minutes; 45 cycles of denaturation 126 (10 seconds at 95 °C) followed by 20 seconds for annealing at 60 °C for faah, abhd4, vtg; 59 °C for 127 dagla, trpv1; 57 °C for napepld; 55 °C for cnr1; 53 °C for gpr55 and mgll; and finally, 20 seconds for 128 elongation at 72 °C.

129 Two *no template control* (NTC) were added in each run to guarantee absence of contamination.

Annealing temperatures (Ta) for each primer were optimized with temperature gradient assays. Primer specificities were assessed with the absence of primer-dimer formation and dissociation curves. Additionally, for each pair of primers, the efficiencies were evaluated with a mix of cDNA (CTRL group) at different concentrations (1:1, 1:10, 1:100, 1:1000).

The reference genes were *rplp0* (ribosomal protein large P0) and *18s* (ribosomal subunit 18s) for ovary, and *rplp0* and *rpl13a* (ribosomal protein L13a) for testes and liver for being their expression stable and abundant along all the experimental groups. List of primers is stated in Table 1 and additional information can be found in Table S1 (Supplemental material).

RT-qPCR results have been analysed with the C_t (cycle threshold) values of both target and reference
 genes with the Delta Delta C_t method [45,46] using the spreadsheet provided by Bio-Rad (Gene
 Expression analysis for iCycler iQ Rela-time PCR detection system version 2.0).

142

143

2.3 Measurement of endocannabinoids (AEA, 2-AG) and endocannabinoid-like mediators (PEA, 144 OEA) in testis and ovary.

145 Endocannabinoids and endocannabinoids-like mediators were extracted, purified and quantified 146 from 5 testis and ovaries as previously described [47,48].

147

148 2.4 Gonad histology and image analysis

149 After being fixed overnight in Bouin, gonads were rinsed and stored in EtOH 70 % till processing. 150 Tissues were dehydrated with an increasing series of EtOH (70-100 %) and embedded in paraffin 151 overnight. Then, the paraffin blocs were sectioned with a microtome (Leica RM2125 RTS) at 4 μ m 152 and stained with Eosin - Mayer's haematoxylin (Bio-Optica). Microphotograpies were taken using a 153 Zeiss Axio Imager.M2 microscope coupled with a high-resolution camera Zeiss Aixocam 105 color. 154 One slide from the anterior, medium and posterior part of the testis and ovaries were chosen for the 155 analysis. Three microphotographies (40x) were taken per slide. Using Image J (ImageJ, NIH, USA, 156 https://imagej.nih.gov/ij/), the percentage of the area occupied by spermatogonia and spermatozoa 157 was evaluated from nine microphotographs per gonad [18] and 5 gonads per experimental group. 158 The area covered with spermatozoa and spermatogonia were manually delimited and evaluated 159 against the total surface of the slide and expressed as percentage. For the oocytes, using Cell Counter 160 plugging (Image J), three classes of oocytes were calculated: previtelogenic oocytes (oogonia and 161 cortical alveoli), vitelogenic oocyte and mature oocyte.

162

163 2.5 Statistical analysis

164 All the data was analysed by one-way analysis of variance (ANOVA) followed by Dunnett's multiple 165 comparison test. When the collected data was expressed in percentage, arcsin transformation was 166 conducted before ANOVA. When data did not meet the conditions for using ANOVA, Kruskall-Wallis 167 (non-parametric test) was applied. Superscript asterisks (*) evidenced statistical differences respect the control (CTRL): * (p < 0.05), ** (p < 0.01). Data are reported as mean ± SEM (Standard Error of the Mean). The statistical software: *GraphPad Prism 6* and *SigmaStat 3.5*. Expression heatmaps of genes were created by fold change means (BPA/CTRL) with *Genesis software v1.7.7*. When fold changes were < 1, values were transformed to the negative inverse following: [-1 / fold change] due to Genesis does not allow to enter values in the 0 - 1 interval (see Supplemental Material 2).

173

174 **3. RESULTS**

3.1 Gonadosomatic index (GSI). In females, the GSI was not affected by BPA (Fig. 1a). However, in
males, the GSI was increased in a dose-dependent manner (Fig. 1b).

178Figure 1. Gonadosomatic Index, female (a) and male (b) treated with 10 and 20 μ g/L BPA. Data are reported as means ±179SEM. Superscript asterisks (*) denote statistically significant differences with respect to the control (CTRL): * (p < 0.05),</td>180** (p < 0.01) (one-way ANOVA, p < 0.05, Dunnett's multiple comparison test).</td>

181

177

3.2 Measurement of endocannabinoids (AEA, 2-AG) and AEA-like mediators (PEA, OEA) in testes and ovaries.

184 In ovary, the levels of AEA were significantly increased following exposure to 10 μ g BPA/L (Table 2).

185 However, OEA was reduced in both BPA groups (10 and 20 μ g/L). In testes, exposure to 20 μ g BPA/L

- 186 significantly reduced the levels of AEA and 2-AG, whereas the lowest concentration of BPA (10 μ g/L)
- 187 was without effect.

AEA expressed as pmol/g tissue, while 2-AG, PEA and OEA as pmol/mg tissue.</td>

3.3 ECS gene transcript levels in gonads.

- **Ovaries.** As shown in Table 3, exposure to BPA did not alter the transcript levels of genes coding for
- 197 the cannabinoid receptors. However, 20 µg BPA/L significantly increased mRNA expression of the
- 198 gene coding for the catabolic enzyme *faah* (Table 3).
- **Table 3.** Relative gene expression of ECS components in zebrafish ovary.

221

214

210

218 **3.4 Vitellogenin transcript levels in the liver.**

219 The highest concentration of BPA increased the mRNA levels of vitellogenin (vtg) in the liver of both

220 male (Figure 3a) and female (Figure 3b) zebrafish.

Figure 3. RT-qPCR results for vtg in zebrafish liver, in males (a) and females (b), following treatment with 10 and 20 μ g/L BPA. Results are expressed as means dCt ± SEM. All data are normalized against the expression levels of *rpl13* and *rplp0* (male) and *rplp0* and 18s (female). Asterisks (*) denote statistically significantly differences with respect to the control

(CTRL): * (p < 0.05); (one-way ANOVA, p < 0.05, Dunnett's multiple comparison test). Levels of mRNA abundance are
 reported in arbitrary units (a.u.).

227

228 **3.5 Relative area covered by spermatozoa and spermatogonia.**

The histological study of zebrafish testes revealed changes in zebrafish testicular development following exposure to BPA (Figure 4a-c). Using image analysis, the area occupied by spermatogonia and spermatozoa were quantified. The 20 µg BPA/L exposure induced a significant decrease of spermatogonia area (Figure 4d) while no effect was observed on the area occupied by spermatozoa (Figure 4e).

234

Figure 4. Histological sections of testis: CTRL group (a), 10 µg/L BPA (b) and 20 µg/L BPA (d). Eosin - Mayer's haematoxylin
 staining. Sg: spermatogonia; Sc: spermatocyte; Sd: spermatid; Sz: spermatozoa. Scale bar: 20 µm. Percentage of zebrafish
 testicular area occupied by spermatogonia (d) and spermatozoa (e). Data reported as means ± SEM. Asterisks (*) denote
 statistically significant differences with respect to the control (CTRL): ** p < 0.01, (one-way ANOVA, p < 0.05, Dunnett's
 multiple comparison test).

240

241 **3.6 Changes in different classes of oocytes**

Using histological analysis, we quantified the proportion of previtellogenic, vitellogenic and mature oocytes in the ovaries of zebrafish exposed to BPA (Figure 5a-c). The results demonstrate that exposure to 10 µg BPA/L significantly augmented the proportion of oocytes in vitellogenic stage, without affecting the percentage of previtellogenic and mature oocytes (Figure 5d-f).

246

Figure 5. Histological sections of zebrafish ovaries, CTRL (a), 10 μ g/L BPA (b) and 20 μ g/L BPA (c). Eosin - Mayer's haematoxylin staining. Prev: previtelogenic oocytes; Vit: Vitellogenic oocytes; Mat: mature oocytes. Scale bar: 200 μ m. Percentage of different classes of oocytes (d-f). Data are reported as mean ± SEM. Asterisks (*) denote statistically significant differences with respect to the control (CTRL): * p < 0.05, (one-way ANOVA, p < 0.05, Dunnett's multiple comparison test).

252

253

4. DISCUSSION

254 Due to the ubiquity of BPA in the environment, several studies have evaluated its adverse responses 255 concerning male and female reproduction [49-51]. Here, we deciphered the effects of two 256 environmental concentrations of BPA (10 and 20 µg/L) on zebrafish gonadal function with emphasis 257 on the ECS. Firstly, our results demonstrate a dose - dependent increase of male GSI. In accordance 258 with previous studies [26,52,53], this support the hypothesis that BPA can alter the testicular 259 development in teleost species. In fact, our observations suggest that the presence of BPA can 260 contribute to accelerate abnormal male testicular development and to unbalance gender patterns, 261 as already reported in zebrafish for BPA and E₂ [54]. However, BPA action on the GSI cannot be 262 generalized due to different results have been reported in different species [27,53,55,56]. It would

appear that duration, window of the exposure, species differences and BPA concentrations are
important factors influencing the effects of BPA on the GSI [53]. In this context, in murine models,
different sensitivities to BPA were observed depending on the mouse strain [57].

266 Hepatic VTG, a yolk precursor protein and a key signal for female reproduction, is another marker for 267 testing the effects of BPA estrogenicity, commonly used for teleosts [58]. Usually, males have low 268 basal or undetectable VTG levels, but exposure to external compounds with estrogen-like activity can 269 stimulate VTG production. Thus, VTG in male fish has become a useful biomarker to assess the 270 presence of environmental compounds with estrogen-like activity. Indeed, several studies have 271 correlated abnormal values of VTG or vtg with BPA in different teleost species [19,27,53,55,59–62]. 272 Specifically, Mandich and coworkers (2007) reported an increase of VTG in plasma in common carps 273 after 14 days of BPA treatment. With zebrafish, 21 day exposure was enough to find an increased 274 gene expression of hepatic vtg in both sexes, similar to what was observed in Sparus aurata after a 275 3-week BPA exposure [26]. Curiously, the increase of vtg transcript (20 µg BPA/L) does not match 276 with the group showing the highest percentage of vitellogenic oocytes (10 µg BPA/L). This may be 277 explained as 1) oocyte maturation is a complex process where VTG is not the only player and other 278 hormones (i.e. FSH, LH) are involved, 2) VTG is a complex protein which undergoes a strong post-279 transcriptional process, and additionally, as cited in [63], the RT-qPCR results do not inform whether 280 the mRNA will be or not be translated into protein.

281

282 The regulation of endocannabinoid tone during the different phases of reproduction is crucial in 283 numerous species [31,33,35,64-66]. However, little information is available regarding the role of AEA 284 tone during oocyte maturation [67]. It is tempting to hypothesize that the AEA produced from the 285 granulosa cells of growing follicles play a role in the control of oocyte maturation in mammals [31]. 286 In the aquatic model, Xenopus laevis, AEA is associated with K⁺ current supression in oocytes (stages 287 V or VI), and consequently, with the inhibition of oocyte responsiveness to gonadotropin and 288 progesterone required for final meiotic maturation [68]. Thus, we may assume that the augmented 289 AEA levels (10 µg BPA/L) may contribute to the signals inducing vitellogenesis but impairing the final 290 oocyte maturation. However, few information is available on the functional role of AEA in teleost 291 ovary, although our hypothesis would be consistent with a previous study [15] demonstrating that 292 10 µg BPA/L is associated with the down-regulation of oocyte maturation signals in female zebrafish. 293 Furthermore, in rodents and humans, the hormonal environment regulates the endocannabinoid 294 production in the gonads [38,69]. Additionally, we observed a decrease in ovarian OEA in the BPA exposed groups. In this context, OEA, which is a AEA-related compound, may be involved in the mammalian follicular maturation [70]. In addition, OEA also plays a role as an anti-inflammatory signal molecule [71,72], suggesting an inflammatory process in the BPA ovaries. In this context, BPAinduced inflammatory responses have been already reported in other species [73].

299

300 Concerning male ECS, reduction in AEA and 2-AG levels was observed following exposure to 20 µg 301 BPA/L in the testis. In male mouse germ cell cultures, the highest levels of 2-AG were observed in 302 spermatogonia and then, such levels were progressively decreased in spermatocytes and spermatids 303 [74]. The latter study is consistent with our findings where the lowest levels of 2-AG were found in 304 the BPA group associated with the reduced area of spermatogonia. In fact, CB2 signaling through 2-305 AG contributes to the normal progression of the spermatogenesis [75]. Focusing on the other 306 endocannabinoid, AEA, Grimaldi and coworkers demonstrated a constant AEA concentration during 307 spermatogenesis (spermatogonia, spermatocyte and spermatids), whereas here we found a 308 decrease in testicular AEA following BPA exposure. Two factors may explain this finding: 1) the 309 observed reduction in AEA was the result of reduced spermatogonia induced by BPA, and/or 2) an 310 increased activity of FAAH (AEA catabolic enzyme) induced by the estrogen-like activity of BPA, 311 reduced the AEA levels. Based on the present results, we cannot distinguish between these two 312 possibilities. Though, similar results were obtained following E₂ treatment in mouse Sertoli cell [76]. 313 Very few studies have quantified testicular cell types, and to date, there are no published 314 observations on the effects of environmental doses of BPA on testicular cell numbers. In zebrafish, 315 higher doses of BPA exclusively reduced the proportion of spermatocytes [18]. Interestingly, our 316 results are in agreement with a study in rats demonstrating that lower concentrations of BPA trigger 317 a reduction in the number of spermatogonia and spermatocytes [21,77]. Furthermore, in male 318 gonads, BPA can induce alterations in miRNAs [78–81] and epigenetic markers, as hyperacetylation 319 of histones and DNA hypermethylation [18], these changes can be also inherited by the offspring and 320 compromise early embryo development depending on the dose and the window of exposure [82,17]. 321 Overall, the present results and those obtained by others in different species suggested that exposure 322 to BPA might be associated with low fertility in male zebrafish and reduced numbers of 323 spermatogonia and spermatogenesis.

324

5. CONCLUSIONS

21-day exposure to environmentally relevant concentrations of BPA induced changes on the ECS. As far as we know, the correct functioning of the ECS is crucial for the normal progression of the reproductive processes in both males and females. Despite of the ECS presence in teleost gonads and its potential role in reproduction, further studies will be needed to fully understand its involvement in fish oogenesis and spermatogenesis. Finally, our results suggested that the ECS may be used as a biomarker for EDC activity related to reproduction.

Habibi: methodology, resources, writing - review funding acquisition; Francesca Maradonna: conceptualization, investigation; Oliana Carnevali: conceptualization, methodology, validation, resources, writing review, supervision, project administration, funding acquisition.

Table S1. Additiona	l information	of primers.
---------------------	---------------	-------------

GENE	Exon span	Amplicon size	Ta (℃)	TISSUE	ZFIN ID	Reference
Cannabinoid receptor 1	No	181	55	ovary, testis	ZDB-GENE-040312-3	[1]
Transient receptor potential cation channel, subfamily V, member 1	Yes	129	59	ovary, testis	ZDB-GENE-030912-8	[2]
G protein-coupled receptor 55	No	91	53	ovary, testis	ZDB-GENE-051113- 260	[3]
N-acyl phosphatidylethanolamine phospholipase D	No	121	57	ovary, testis	ZDB-GENE-030131- 3856	[1]
Monoglyceride lipase	No	118	53	ovary, testis	ZDB-GENE-031006-9	[1]
Fatty acid amide hydrolase	No	202	60	ovary, testis	ZDB-GENE-070619-3	[4]
Diacylglycerol lipase alpha	No	58	59	ovary, testis	ZDB-GENE-070619-1	[1]
Abhydrolase domain containing 4	Yes	132	60	ovary, testis	ZDB-GENE-050417- 83	[4]
Vitellogenin 1	Yes	209	60	liver	ZDB-GENE-001201-1	[5]
Ribosomal subunit 18s	No	90	55	ovary, liver	ZDB-GENE-070410-9	[6]
Ribosomal protein large PO	No	160	60	ovary, testis, liver	ZDB-GENE-000629-1	[5]
Ribosomal protein L13a	Yes	147	59	testis, liver	ZDB-GENE-030131- 168	[7]
