## 41 **Abstract**

42 *Introduction:* Drug-induced block of the hERG potassium channel could predispose to torsade  
43 de pointes, depending on occurrence of concomitant blocks of the calcium and/or sodium  
44 channels. Since the hERG potassium channel block affects cardiac repolarization, the aim of  
45 this study was to propose a new reliable index for non-invasive assessment of drug-induced  
46 hERG potassium channel block based on electrocardiographic T-wave features.

47 *Methods:*  $ERD_{30\%}$  (early repolarization duration) and  $T_{S/A}$  (down-going T-wave slope to T-  
48 wave amplitude ratio) features were measured in 22 healthy subjects who received, in different  
49 days, doses of dofetilide, ranolazine, verapamil and quinidine (all being hERG potassium  
50 channel blockers and the latter three being also blockers of calcium and/or sodium channels)  
51 while undergoing continuous electrocardiographic acquisition from which  $ERD_{30\%}$  and  $T_{S/A}$   
52 were evaluated in fifteen time points during the 24 hours following drug administration (“ECG  
53 Effects of Ranolazine, Dofetilide, Verapamil, and Quinidine in Healthy Subjects” database by  
54 Physionet). A total of 1320 pairs of  $ERD_{30\%}$  and  $T_{S/A}$  measurements, divided in training (50%)  
55 and testing (50%) datasets, were obtained. Drug-induced hERG potassium channel block was  
56 modelled by the regression equation  $B_{ECG}(\%)=a \cdot ERD_{30\%}+b \cdot T_{S/A}+c \cdot ERD_{30\%} \cdot T_{S/A}+d$ ;  $B_{ECG}(\%)$   
57 values were compared to plasma-based measurements,  $B_{REF}(\%)$ .

58 *Results:* Regression coefficients values, obtained on the training dataset, were:  $a=-561.0 \text{ s}^{-1}$ ,  
59  $b=-9.7 \text{ s}$ ,  $c=77.2$  and  $d=138.9$ . In the testing dataset, correlation coefficient between  $B_{ECG}(\%)$   
60 and  $B_{REF}(\%)$  was 0.67 ( $p<10^{-81}$ ); estimation error was  $-11.5 \pm 16.7\%$ .

61 *Conclusion:*  $B_{ECG}(\%)$  is a reliable non-invasive index for the assessment of drug-induced hERG  
62 potassium channel block, independently from concomitant blocks of other ions.

## 66 **Introduction**

67 Drugs belonging to several therapeutic classes, among which antiarrhythmics, antibiotics,  
68 antipsychotics and anticancer agents, have side-effects which may cause serious ventricular  
69 tachyarrhythmias, such as torsade de pointes (TdP) [1]. Among antiarrhythmics drugs,  
70 dofetilide is the one with the highest risk of TdP, quantified in 1÷5% of exposed subjects [2].  
71 By contrast, antibiotics, antipsychotics and other classes of ‘non-cardiovascular drugs’ provoke  
72 TdP less frequently [1]. All these drugs cause block of the human Ether-à-go-go-related gene  
73 (hERG) potassium channels, which conduct the rapid component of the delayed rectifier  
74 potassium current  $I_{Kr}$  (outward current), the major responsible of cardiac repolarization [3];  
75 difference in TdP risk in drug-induced hERG potassium channel block can be ascribed to the  
76 presence of concurrent block of calcium and/or sodium channels (inward currents) [4].

77 All the drugs increasing the risk of TdP induce a prolongation of cardiac myocytes action  
78 potential which could result in a prolonged repolarization, and thus in a prolonged QT interval  
79 on the electrocardiogram (ECG) known as drug-induced long QT syndrome (diLQTS). The  
80 occurrence of diLQTS represents one of the most common reasons for drug withdrawal or  
81 relabeling, so that it is highly investigated in drug development [1,5]. However, the observation  
82 that some drugs block the hERG potassium channel and prolong QT with minimal TdP risk led  
83 to the conclusion that QT prolongation is not a specific clue of TdP risk [4]. Thus, further  
84 effects on cardiac repolarization (which will reflect on variations of the T-wave morphology  
85 on the ECG) are expected to occur.

86 ECG-based features describing T-wave morphology other than QT interval have been  
87 proven useful in characterizing drug-induced channel block. In particular, in a recent study on  
88 drug safety, an index based on T-wave down slope and T-wave amplitude has been proposed  
89 as an alternative metric for measuring the level of hERG potassium channel block, independent  
90 from concomitant calcium and/or sodium channels block [6]. However, previous studies

91 showed that hERG potassium channel block equally prolongs early (left T-wave half) and late  
92 repolarization (right T-wave half) [7], thus indicating that other ECG-based metrics should be  
93 considered in addition to the down-going T-wave slope and the T-wave amplitude to better  
94 quantify hERG potassium-channel block.

95 A recent study by our group [8] that used an approach based on artificial neural networks,  
96 confirmed that T-wave features on both right and left T-wave sides are necessary to provide a  
97 reliable classification of hERG potassium-channel block; in particular the features chosen as  
98 input of the artificial neural network were  $ERD_{30\%}$  (defined as the 30% early phase of  
99 repolarization duration and describing left T-wave side) and  $T_{S/A}$  (representing the down-going  
100 T-wave slope to T-wave amplitude ratio). Such approach has the advantage of providing a  
101 reliable and non-invasive classification of hERG potassium-channel block; however, it cannot  
102 determine the block level point estimate and requires specific expertise from the operator to be  
103 applied. Thus, the aim of this study was to propose a new index that can be computed through  
104 a simple formula and not requiring computational modelling techniques [9], for the reliable  
105 assessment of drug-induced hERG potassium channel block based on T-wave features on both  
106 right and left T-wave sides in condition of single-drug assumption.

## 107 **Materials and Methods**

### 108 *Study Population and Clinical Data*

109 Study population consisted of 22 healthy subjects who received, in different days separated by  
110 7-day wash out periods, single doses of dofetilide (500  $\mu$ g; Tikosyn, Pfizer, New York, NY),  
111 ranolazine (1500 mg; Ranexa, Gilead, Foster City, CA), verapamil hydrochloride (120 mg;  
112 Heritage Pharmaceuticals, Edison, NJ) and quinidine sulfate (400 mg; Watson Pharma,  
113 Corona, CA). While dofetilide blocks hERG potassium channel only, the other drugs also block  
114 calcium or sodium channels. Drug administration was performed under fasting conditions

115 while undergoing continuous ECG acquisition (sampling frequency: 500 Hz; amplitude  
116 resolution: 2.5  $\mu\text{V}$ ). From each continuous recording, triplicate 10-s 12-lead ECG segments  
117 were extracted at fifteen post-dose points (+0.5 h; +1.0 h; +1.5 h; +2.0 h; +2.5 h; +3.0 h; +3.5  
118 h; +4.0 h; +5.0 h; +6.0 h; +7.0 h; +8.0 h; +12.0 h; +14.0 h; +24.0 h). The vectorcardiographic  
119 (VCG) median beat derived from each 10-s ECG segment was considered representative of the  
120 segment itself and used for features extraction. Therefore, 3960 (22 subjects by 3 ECG  
121 recordings by 15 time points by 4 drugs) VCG median beats were analyzed. Additionally, at  
122 the same fifteen time points a blood sample was drawn for pharmacokinetic analysis. All VCG  
123 and plasma data are available at the “ECG Effects of Ranolazine, Dofetilide, Verapamil, and  
124 Quinidine in Healthy Subjects” database by Physionet [7,10]. All Physionet data were fully de-  
125 identified and randomized, and can be used with no further independent ethics committee  
126 approval.

127

### 128 *ECG-based Index for Assessment of Drug-induced hERG Potassium Channel Block*

129 The new proposed ECG-based index of drug-induced hERG potassium channel block,  
130  $B_{ECG}(\%)$ , is modelled by the following regression equation:

$$131 \quad B_{ECG}(\%) = a \cdot ERD_{30\%} + b \cdot T_{S/A} + c \cdot ERD_{30\%} \cdot T_{S/A} + d \quad (1)$$

132 where:  $ERD_{30\%}$  (s) represents the 30% early repolarization duration [11];  $T_{S/A}$  ( $\text{s}^{-1}$ ) represents  
133 the ratio of down-going T-wave slope ( $T_{RS}$ ,  $\text{mV} \cdot \text{s}^{-1}$ ) and T-wave amplitude ( $T_A$ , mV) [6]; and  
134 a, b, c and d represent the model parameters to be estimated.  $T_{RS}$  is a downslope, thus being its  
135 sign negative, it was computed as the absolute value of the mean first derivative of the T wave  
136 in the interval from the T-wave peak to T-wave end ( $T_p T_e$ ; s).

137 Experimental values of  $ERD_{30\%}$  and  $T_{S/A}$  were obtained for all the 3960 VCG median beats.  
138 Specifically,  $ERD_{30\%}$  together with  $T_A$ , and  $T_p T_e$  values for each VCG median beat are reported

139 in the Physionet database [7,10]; the formers were used for calculation of  $T_{S/A}$  according to  
140 definition ( $T_{S/A}=I/T_pT_e$ ). Then, for each subject, the associated values of  $ERD_{30\%}$  and  $T_{S/A}$  for  
141 each of the fifteen time points relative to a drug administration were computed by averaging  
142 the values obtained from the VCG median values obtained from triplicate ECGs.

### 143 *Plasma-based Index for Assessment of Drug-induced hERG Potassium Channel Block*

144 The reference index of hERG potassium channel block,  $B_{REF}(\%)$ , at plasma drug concentration  
145  $D$  (the values of which, for the fifteen post-dose time points, are available in the database) was  
146 obtained through the Hill equation [11]:

$$147 \quad B_{REF}(\%) = 100 \cdot \frac{D^n}{IC_{50} + D^n} \quad (2)$$

148 where  $IC_{50}$  is the concentration of drug that causes 50% block, and  $n$  is the Hill coefficient.  
149  $IC_{50}$  and  $n$  are equal to 1 nM and 0.6, 6490 nM and 0.8, 499 nM and 1.1, and 343 nM and 1.0,  
150 for dofetilide, ranolazine, verapamil, and quinidine, respectively [12].

### 151 *Statistical Analysis*

152 To determine the a, b, c, and d regression coefficients of Eq. (1), multiple regression analysis  
153 with interaction effects was performed between the two predictors,  $ERD_{30\%}$  and  $T_{S/A}$ , and  
154  $B_{REF}(\%)$ ; coefficient of determination ( $R^2$ ) and statistical significance of the impact of each  
155 term on the prediction were computed.

156 The database was randomly divided in two datasets: 50% (corresponding to 660 pairs of  
157  $ERD_{30\%}$  and  $T_{S/A}$  values from 11 subjects) was used as training dataset to build the model; the  
158 remaining 50% was used as testing dataset. Correlation between  $B_{ECG}(\%)$  and  $B_{REF}(\%)$  in the  
159 training and testing datasets was performed by computation of the Pearson Product Moment  
160 correlation coefficient ( $r$ ); slope and intercept of the regression line, together with their  
161 corresponding 95% confidence intervals ( $CI$ ), was also computed. The Lilliefors test was used

162 to evaluate the hypothesis that each variable had a normal distribution with unspecified mean  
163 and variance. Normal distributions were described in terms of mean  $\pm$  standard deviation, while  
164 not-normal distributions were described in terms of 50<sup>th</sup> [25<sup>th</sup>; 75<sup>th</sup>] percentiles. Bland Altman  
165 plot was used to evaluate the degree of agreement between  $B_{ECG}(\%)$  and  $B_{REF}(\%)$ .

166 Eventually, estimation error of hERG channel block provided by  $B_{ECG}(\%)$  in different block  
167 classes (<25%; 25%÷50%; >50%; defined according to  $B_{REF}(\%)$ ) was computed as signed  
168 difference between  $B_{ECG}(\%)$  and  $B_{REF}(\%)$ . The statistical significance level was set at 5%  
169 ( $p<0.05$ ) in all cases.

## 170 **Results**

171  $D$ ,  $B_{REF}(\%)$ ,  $ERD_{30\%}$  and  $T_{S/A}$  distributions over the 24 hours after the administration of the 4  
172 drugs for all 22 subjects are depicted in Fig. 1. Overall,  $B_{REF}(\%)$  varied from 0.4% to 76.9%  
173 (36.4%[19.1%;53.5%]); similar distributions were observed in the training dataset, where  
174  $B_{REF}(\%)$  varied from 0.4% to 76.9% (39.3%[20.9%;55.0%]), and in the testing dataset, where  
175  $B_{REF}(\%)$  varied from 0.4% to 75.5% (34.3%[17.3%;49.2%]).

176 Proportion of variance explained by the two predictors in the training dataset was equal to 57%  
177 ( $R^2=0.57$ ). From the multiple regression analysis, regression coefficients (with their statistical  
178 significance) were found as  $a=-561.0 \text{ s}^{-1}$  ( $p=0.002$ ),  $b=-9.7$  ( $p<10^{-24}$ ) s,  $c=77.2$  ( $p=1.31 \cdot 10^{-5}$ )  
179 and  $d= 138.9$  ( $p<10^{-36}$ ), yielding:

$$180 \quad B_{ECG}(\%) = -561.0 \cdot ERD_{30\%} - 9.7 \cdot T_{S/A} + 77.2 \cdot ERD_{30\%} \cdot T_{S/A} + 138.9 \quad (3)$$

181 A positive significant linear correlation was found between  $B_{ECG}(\%)$  and  $B_{REF}(\%)$  in both  
182 training dataset ( $r=0.75$ ,  $p<10^{-119}$ ) and testing dataset ( $r=0.67$ ,  $p<10^{-81}$ ; Fig. 2). Regression-line  
183 slope and intercept were 1.0 ( $CI: 0.9\div 1.1$ ) and 0.0 ( $CI: -2.8\div 2.8$ ) in the training dataset, and 0.9  
184 ( $CI: 0.8\div 1.0$ ) and -6.1 ( $CI: -9.9\div -2.2$ ) in the testing dataset.

185 Figs. 3 and 4 show Bland Altman plots for the agreement evaluation of  $B_{ECG}(\%)$  and  
186  $B_{REF}(\%)$  for the training and testing datasets considering all the drugs, and for the testing dataset  
187 considering each single drug separately. Eventually, estimation errors of  $B_{ECG}(\%)$  with respect  
188 to  $B_{REF}(\%)$  in various hERG-channel-block classes are reported in Table 1; estimation was  
189 more accurate for classes with higher hERG potassium channel block.

## 190 Discussion

191 This study presented and validated a new index,  $B_{ECG}(\%)$ , based on  $ERD_{30\%}$  and  $T_{S/A}$  for the  
192 assessment of drug-induced hERG potassium channel block, possibly with concomitant block  
193 of other ions channels. Used drugs were: dofetilide, which is a strong pure hERG potassium  
194 channel blocker; ranolazine, which is a blocker of the hERG potassium channel as well as of  
195 the late sodium channel; verapamil, which is a blocker of the hERG potassium channel as well  
196 as of the calcium channel; and quinidine, which is a blocker of the hERG potassium channel  
197 as well as of the late sodium channel and of the calcium channel. To evaluate  $B_{ECG}(\%)$   
198 reliability, results were compared against those obtained with a reference index,  $B_{REF}(\%)$ .  
199  $B_{ECG}(\%)$  and  $B_{REF}(\%)$  were significantly correlated (Fig. 2) and showed very good agreement  
200 (Fig. 3), so that they can be considered substantially equivalent. Highest  $B_{ECG}(\%)$  performance  
201 was observed in the high percentage block class (Table 1), which is also the one possibly  
202 associated to higher cardiac risk.

203 Initially, all the features that correlate with hERG channel block were evaluated as possible  
204 predictors in the index formulation:  $ERD_{30\%}$ ,  $LRD_{30\%}$  (i.e. 30% late repolarization delay),  $T_{S/A}$   
205 and  $T_pT_e$ . To these features, we added ECG features showing correlation with blood potassium  
206 concentration. Indeed, hERG channel block mimics hypokalemia (by reducing potassium  
207 outflow current), and both the hERG block and hypokalemia result in QT-interval prolongation  
208 and reduced T-wave amplitude [6,13]. In this regard, previous studies showed that blood

209 potassium concentration correlates with several T-wave features [14,15]. Eventually, only two  
210 independent (from multicollinearity testing) ECG features were selected here for the index  
211 formulation:  $ERD_{30\%}$  and  $T_{S/A}$ .  $T_{S/A}$  was chosen since conceptually similar indexes were found  
212 to be predictors of both hERG channel block and blood potassium level [6,14].  $ERD_{30\%}$  was  
213 chosen in addition to  $T_{S/A}$  because it is a feature related to early repolarization, differently from  
214  $T_{S/A}$  which describes late repolarization. Adding  $ERD_{30\%}$  to  $T_{S/A}$  further improves the already  
215 reliable assessment of hERG channel block by  $T_{S/A}$  alone. Indeed, unreported results indicate  
216 that linear regression analysis performed using only  $T_{S/A}$  provides a coefficient of determination  
217  $R^2=0.55$ , slightly lower than the one resulting from the model of this study ( $R^2=0.57$ ). This  $R^2$   
218 improvement may appear limited but the statistical significance of the p-value related to  
219  $ERD_{30\%}$  ( $p=0.002$ ) demonstrates that this ECG feature has a significant impact on the prediction  
220 of drug-induced hERG potassium channel block. Thus, although  $T_{S/A}$  represents the most  
221 important component, it is necessary to use both  $T_{S/A}$  and  $ERD_{30\%}$  features in order to optimize  
222 assessment of the hERG potassium channel block. All the other evaluated ECG features  
223 mentioned above were rejected because of their positive multicollinearity with  $ERD_{30\%}$  and/or  
224  $T_{S/A}$ .

225 The two selected ECG features,  $ERD_{30\%}$  and  $T_{S/A}$ , have been previously used in the same  
226 context to provide a classification between “low” and “high” block values [8]. The method  
227 used in [8] was based on artificial neural networks, a typical non-linear data-driven model.  
228 Similarly, in this study, the  $B_{ECG}(\%)$  prediction obtained using only the sum of the  $ERD_{30\%}$  and  
229  $T_{S/A}$  linear contributions ( $R^2=0.55$ ) was lower than that obtained using both the sum of  $ERD_{30\%}$   
230 and  $T_{S/A}$  linear contributions and their bilinear contribution ( $R^2=0.57$ ), as in Eq. (1). Being the  
231 p-value associated to the bilinear contribution statistically significant ( $p=1.31 \text{ our} \cdot 10^{-5}$ ), the  
232 improvement of  $R^2$  is also statistically significant. Additionally,  $ERD_{30\%}$  and  $T_{S/A}$  direct values  
233 were used here, differently from what done in [8] and usually in clinical practice, where their

234 differential values with respect to the pre-dose values were used [8]. Indeed, use of serial  
235 electrocardiography [16] in Eq. (1) significantly reduces the predictive performances of the  
236 model ( $R^2=0.39$ ). However, the model here designed is meant to be simultaneously valid for  
237 different drugs with highly different effects (Fig. 1); ECG variations with respect to pre-dose  
238 values may be strongly dependent on the specific drug and may act as confounding factor. This  
239 fact, associated to the presence of an interaction (bilinear) term in our linear regression model,  
240 could explain the lower performance obtained with differential values and justify the use of  
241 absolute values which provide better results.

242 Goodness of our results can be discussed by comparing them with results obtained  
243 considering predictive quantitative structure–activity relationship (QSAR) models [9], which  
244 are computational modeling methods traditionally developed for revealing relationships  
245 between structural properties of chemical compounds and biological activities. We obtained  
246  $R^2=0.57$  whereas QSAR regression models for hERG blockage in general exhibit predictive  
247 powers between  $R^2=0.5$  and  $R^2=0.7$  [9]. Thus, the value we obtained appears to be comparable  
248 to those traditionally achieved in QSAR models but we have to underline that the method  
249 proposed in the present study is based on an indirect measure of hERG blockage from ECG  
250 features. Indeed, use of this method may avoid complex, invasive and expensive experiments.

251 It has to be noted that heart rate may affect estimation of repolarization endpoints [17,18]  
252 and thus of  $ERD_{30\%}$  and/or  $T_pT_e$  and thus  $T_{S/A}$ . However, it was shown that neither  $ERD_{30\%}$   
253 [11] nor  $T_pT_e$  [7] are heart rate dependent.

254 Other ECG biomarkers have been proposed to study drug effects on cardiac ventricular  
255 repolarization. For example, the recently proposed T-vector velocity [19,20] provides insights  
256 on the mechanistic link between drug effects on ionic currents and overall repolarization on the  
257 ECG. Differently, the here proposed approach is the first, to the best of our knowledge, to  
258 provide the point estimate of block level relating to the hERG potassium-channel. Future

259 studies on larger populations, possibly undergoing administration of other drugs are needed to  
260 confirm reliability of  $B_{ECG}(\%)$  index to assess hERG potassium channel block and its associated  
261 cardiovascular risk also with indexes different from the QT interval, such as T-wave alternans  
262 [21]. Finally, the index presented in this study was designed to predict hERG channel block  
263 only, thus it can be applied to investigate if a novel drug blocks the hERG potassium channel.  
264 Although it was shown that this index provides reliable results in case of drugs that are not pure  
265 hERG blockers (and thus characterized by lower values of block), in future studies the  
266 reliability of the proposed index should be also evaluated and possibly updated in known non-  
267 hERG blocker drugs to avoid the risk of detecting false condition of block. The index, by itself,  
268 cannot improve risk assessment since risk due to hERG channel block can be mitigated by  
269 other ion current change. However, the adopted methodology represents the first step for the  
270 development of a complete assessment of ion-specific indexes able to noninvasively predict  
271 ion channel blocks. When all these indexes will be available, they will provide detailed  
272 information on the drug effect on each ion channel and will support noninvasive assessment of  
273 proarrhythmia risk.

## 274 **Conclusion**

275 A novel ECG-based index for the assessment of drug-induced hERG potassium channel  
276 block, independently from concomitant blocks of other ions, has been proposed. This new  
277 index focuses on the characterization of both early and late ventricular repolarization changes  
278 and represents a step forward in the characterization of drug effects on human cardiac  
279 repolarization.

358 **FIGURE LEGENDS**

359 **Figure 1.**  $D$ ,  $B_{REF}(\%)$ ,  $ERD_{30\%}$  and  $T_{S/A}$  distributions over the 24 hours after the administration  
360 of the dofetilide, ranolazine, verapamil and quinidine for all 22 subjects (grey lines; black bold  
361 line represents the mean trend over population).

362

363 **Figure 2.** Linear regression plots between  $B_{REF}(\%)$  and  $B_{ECG}(\%)$  in the training and testing  
364 datasets. Regression line ( $x=B_{ECG}(\%)$ ;  $y=B_{REF}(\%)$ ) and correlation coefficient ( $r$ ) are also  
365 reported.

366

367 **Figure 3.** Bland-Altman plots for the testing and training datasets. Mean: mean value of  
368  $B_{ECG}(\%)$  and  $B_{REF}(\%)$ ; estimation error: difference between  $B_{ECG}(\%)$  and  $B_{REF}(\%)$ . Continuous  
369 lines represent mean estimation errors; dotted lines represent  $\text{mean} \pm 1.96 \cdot \text{standard deviation}$   
370 values of estimation errors.

371

372 **Figure 4.** Bland-Altman plots for the testing dataset considering each single drug separately:  
373 A) Dofetilide, B) Ranolazine, C) Verapamil, D) Quinidine. Mean: mean value of  $B_{ECG}(\%)$   
374 and  $B_{REF}(\%)$ ; estimation error: difference between  $B_{ECG}(\%)$  and  $B_{REF}(\%)$ . Continuous lines  
375 represent mean estimation errors; dotted lines represent  $\text{mean} \pm 1.96 \cdot \text{standard deviation}$   
376 values of estimation errors.

**Table 1.** Errors in the estimation of hERG channel block, computes as difference between  $B_{ECG}(\%)$  and  $B_{REF}(\%)$ .

Block class	Estimation error (%)
<25%	-23.3±12.0
25-50%	-11.0±14.8
>50%	5.3±9.4
0-100%	-11.5±16.7
