# 43 Abstract

Consumers are increasingly aware of the importance of regular consumption of fresh fruit in 44 their diet. Since fresh fruit are highly sensitive to postharvest decay, several investigations 45 focused on the study natural compounds alternative to synthetic fungicides, to extend their shelf 46 life. A long list of studies reported the effectiveness of the natural biopolymer chitosan in 47 control of postharvest diseases of fresh fruit. However, these findings remain controversial, 48 49 with many mixed claims in the literature. In this work, we used random-effects meta-analysis to investigate the effects of 1% chitosan on (i) postharvest decay incidence; (ii) mycelium 50 51 growth of fungal pathogens Botrytis cinerea, Penicillium spp., Colletotrichum spp. and 52 Alternaria spp.; and (iii) phenylalanine ammonia-lyase, chitinase and  $\beta$ -1,3-glucanase activities. Chitosan significantly reduced postharvest disease incidence (mean difference [MD], 53 -30.22; P <0.00001) and *in-vitro* mycelium growth (MD, -54.32; P <0.00001). For host 54 defence responses, there were significantly increased activities of  $\beta$ -1,3-glucanase (MD, 55 115.06; P = 0.003) and chitinase (MD, 75.95; P < 0.0002). This systematic review contributes 56 to confirm the multiple mechanisms of mechanisms of action of chitosan, which has unique 57 properties in the natural compound panorama. Chitosan thus represents a model plant protection 58 59 biopolymer for sustainable control of postharvest decay of fresh fruit.

protection; sustainable control of plant pathogens

#### 64 **1 INTRODUCTION**

65

Postharvest fungal diseases can limit the storage period and shelf life, and thus market life, of 66 fruit and vegetables, which results in serious economic losses worldwide (Oerke & Dehne, 67 2004; Romanazzi, Smilanick, Feliziani, & Droby, 2016; Palou & Smilanick, 2020). The global 68 average loss due to the food postharvest reported by Food and Agriculture Organization, was 69 estimated in North America, Europe and Oceania about 29%, compared to an average of about 70 38% in industrialized Asia, Africa, Latin America and South East Asia (Parfitt, Barthel, & 71 Macnaughton, 2010; Food and Agriculture Organization of the United Nations, 2011; Sawicka, 72 73 2019).

74 The main fungal diseases (and their associated fungal pathogen) include: gray mold (Botrytis cinerea Pers.); Rhizopus rot (Rhizopus stolonifer Ehrenb.); anthracnose 75 (Colletotrichum spp.); green mold (Penicillium digitatum Pers.); blue mold (Penicillium 76 italicum Wehmer on citrus fruit, P. expansum Link on other fruit); and Alternaria rot 77 (Alternaria spp.). The control of the causal fungal pathogens is therefore critical to extend the 78 shelf-life of these fresh products (Prusky, 2011; Arah, Amaglo, Kumah, & Ofori, 2015). Despite 79 80 the efficacy of synthetic fungicides in the control of postharvest decay, public concerns about 81 chemical and toxic residues in food (Belden, McMurry, Smith, & Reilley, 2010; Mebdoua, 2018; Goncalves et al., 2019; Liu, Yamdeu, Gong, & Orfila, 2020) and the increase in drug-82 resistant strains of many pathogens (Zuccolo et al., 2019) indicate the need for development of 83 84 new strategies. Over the last few decades, there has been an increasing interest in the study of postharvest control methods that make use of natural resources (Palou, Smilanick & Droby, 85 2008; Talibi, Boubaker, Boudyach, & Ait Ben Aoumar, 2014; Souza, Yuk, Khoo, & Zhou, 86 2015; Guimarães, Abrunhosa, Pastrana, & Cerqueira, 2018; Ebrahimzadeh & Abrinbana, 2019; 87 Liu et al., 2019; Liu, et al., 2020). Such alternative compounds can act as resistance inducers 88

and/or activators of plant defence mechanisms, or they can have strong antimicrobial activities 89 90 against the main postharvest fungal pathogens (Romanazzi, Feliziani, Baños, & Sivakumar, 91 2017; Ribes, Fuentes, Talens, & Barat, 2018). However, only a few such natural fungicides have been approved for use as control agents for postharvest diseases, due to the strict 92 93 regulatory policies for food safety. Among these, chitosan is a natural biocompatible polysaccharide emerged as a promising eco-friendly alternative to synthetic fungicides 94 (Muzzarelli,1983; Romanazzi, Feliziani, & Sivakumar, 2018; Betchem, Johnson, & Wang, 95 2019). To give some background, chitosan is a common name for the polysaccharide N-aceyl-96 D-glucosamine (Zargar, Asghari, & Dashti, 2015). The chitosan compound is obtained by 97 98 deacetilation of chitin through exposure to NaOH solutions or to the enzyme chitinase. It is a 99 functional cationic biopolymer that is widely studied and used across the world. Chitosan have many applications included food industry (Gutiérrez, 2017; da Silva, de Souza, & Dantas 100 101 Lacerda, 2019; Morin-Crini, Lichtfouse, Torri, & Crini, 2019; Kabanov, & Novinyuk, 2020), cosmetology (Aranaz et al., 2018; Kaczmarek, Struszczyk-Swita, Li, Szczęsna-Antczak, & 102 Daroch, 2019) and human medicine (Tungland & Meyer, 2002; Leung, Liu, Koon, & Fung, 103 2006; Kofuji et al., 2010; Zhao et al., 2018). 104

105 Concerning the agriculture applications, the chitosan was the first compound in the list 106 of basic substances approved in the European Union for plant protection purposes (Reg. EU 66 107 2014/563), for both organic agriculture and integrated pest management. For several years now, 108 chitosan has been of interest in many studies that have shown that it can be used to prolong 109 storage of an array of fruit and vegetables worldwide, where it has been shown to have three major activities: including biofilm formation on treated surfaces (El Ghaouth, Arul, 110 111 Ponnampalam, & Boulet, 1991; Valencia-Chamorro, Palou, & Del Río, 2011; Romanazzi et al., 2018); as an antimicrobial (Goy, De Britto, & Assis, 2009; Kong, Chen, Xing, & Park, 2010; 112 Feliziani, Landi, & Romanazzi, 2015; Cheung, Ng, Wong, & Chan, 2015; Wang, Li, & Zhang, 113

2017; Pétriacq, López, & Luna, 2018; Duan et al., 2019); and as an elicitor of host defence
mechanisms (Landi, Feliziani, & Romanazzi, 2014; Coqueiro et al., 2015; Landi et al., 2017;
Colman et al., 2019; Xoca-Orozco et al., 2019; Obianom, Romanazzi, & Sivakumar, 2019). For
these reasons, chitosan can be used as a biodegradable fungicide (Rebelo, Vila, & Fangueiro,
R., 2016; Liang et al., 2017).

However, the heterogeneity of chitosan activities and its effectiveness across a wide 119 120 range of experimental conditions have led to different interpretations of its primary use/ mechanism/ actions. As a result, different recommendations for chitosan treatments have been 121 provided (Ramos-García et al., 2012; Bill, Sivakumar, Korsten, & Thompson, 2014; Xing et 122 123 al., 2016; Flores et al., 2018; Betchem et al., 2019; de Souza, Lundgren, de Oliveira, Berger, & 124 Magnani, 2019). Furthermore, based on reports of the evaluation of chitosan across similar and different fungal strains, its value for disease reduction can vary (Herrera-Romero, Ruales, & 125 Caviedes, 2017; Hua et al., 2019; Zahid, Maqbool, Ali, Siddiqui, & Bhatti, 2019). Also, despite 126 127 the many studies in the literature that have investigated a wide range of chitosan treatments and their influences, no single study has made all of the appropriate comparisons for a full 128 evaluation. Thus, given the mixed claims in the literature, there is the need to define the overall 129 130 effectiveness of chitosan, to highlight useful aspects for its future investigation.

Meta-analyses can be applied as a tool for analysis of large amounts of data across many primary studies, in which the main purpose is to integrate and interpret the findings, to provide conclusions that the individual studies alone cannot show clearly. This statistical procedure provides an integration of the data across several to many independent studies (Maestri, Pavlicevic, Montorsi, & Marmiroli, 2019). The combination of the resulting outcomes can also increase the statistical power, and make it possible to detect relatively small effects (Rosenberg, Garrett, Su, & Bowden, 2004; Nelson, Gent, & Grove., 2015; Schwingshackl, Hoffmann, Iqbal, 138 Schwedhelm, & Boeing, 2018; Chen, Chen, Chen, & Huang, 2019; González-Domínguez et139 al., 2019).

140 The aim of the present study was to carry out a meta-analysis to quantitatively review the data across the available studies on the effectiveness of 1% chitosan, the most common 141 142 concentration that has been tested in the control of postharvest decay (Romanazzi et al., 2018). Hence, the objectives were to determine the effectiveness of 1% chitosan on: (i) reduction of 143 postharvest diseases of fresh fruit; (ii) in-vitro mycelium growth of the causal agents of 144 postharvest decay; and (iii) phenylalanine ammonia-lyase (PAL), β-1,3-glucanase and chitinase 145 activities associated with host defence mechanisms against these causal agents at 24 h post-146 147 treatment (hpt).

148

# 149 **2. METHODS**

150

# 2.1 Search strategy and study selection

A systematic literature search from 2007 to 2019 was performed using the databases of Scopus and Web of Science and the following terms: 'chitosan' and 'fruit'. Studies that used chitosan mixed with other compounds were not considered. The selection of studies was conducted according to the Preferred Reporting Items for Systematic Reviews and Meta-analyses (PRISMA) guidelines (Moher, Liberati, Tetzlaff, Altman, & PRISMA Group, 2009).

Article selection for the meta-analysis used the following inclusion criteria: 1% chitosan; disease incidence; *in-vitro* mycelium growth according to specific postharvest fungi; and activity of the enzymes involved in plant defence mechanisms. The eligibility of the articles was assessed, with the exclusion of the studies with different chitosan concentrations, with no information on disease incidence, mycelium growth or defence enzymes, and with no known fungal species.

In more detail, three categories were included for the studies related to: (i) disease 162 incidence published from 2010 to 2019, caused by gray mold, Rhizopus rot, anthracnose, 163 green/blue mold and/or Alternaria rot, considered as subgroups; (ii) in-vitro mycelium growth 164 published from 2007 to 2019 for the decay causing fungal pathogens B. cinerea, Penicillium 165 spp., Colletotrichum spp. and Alternaria spp., considered as subgroups; (iii) enzyme activities 166 associated with host defence mechanisms analysed at 24 hpt published from 2009 to 2018, for 167 PAL, chitinase and  $\beta$ -1,3-glucanase, considered as subgroups. All of the studies included at 168 169 least two treatments, as an untreated control and the 1% chitosan treatment. The fruit varieties, the 1% chitosan application and the detection timing varied across these studies. In some 170 171 studies, the treatment application times and rates were reported. In such cases, only the treatments applied at the same time as the standard treatment were considered in the meta-172 analysis. The risk of bias and test for asymmetry for the funnel plots were used to evaluate the 173 publication bias. Cochran's I<sup>2</sup> indices, Tau<sup>2</sup> and  $\chi^2$  tests were used to estimate the statistical 174 heterogeneity of the studies (Tufanaru, Munn, Stephenson, & Aromataris, 2015). If the 175 heterogeneity was significant (I<sup>2</sup> >75%; and/or P <0.05), a random effects model was applied 176 to all of the subgroups included in the postharvest decay disease incidence, the decay causing 177 fungi mycelium growth, and the defence enzyme activity categories. 178

179

# 180 2.2 Data extraction

Data were recorded from the same days of chitosan treatments in each study. All of the studies that were related to the effects of chitosan towards disease incidence were calculated as percentage effects. The studies on the effects on mycelium growth resulted on three different measurement units (percentage, mm, cm), and again these were converted to percentages. To unify the different measurement units used across the studies of the defence enzyme activities, the values were converted into percentage of the mean (% mean) with respect to the normal

187 control ([treatment mean/ normal control mean]  $\times$  100) (Viswanatha, Shylaj, & Moolemath, 188 2017). If the standard deviations (SDs) or standard errors (SEs) were not reported, the data were 189 transformed according to the P values (Weir et al., 2018). Data were extracted from the Figures presented in the papers using Plot Digitiser software (Kadic, Vucic, Dosenovic, Sapunar, & 190 191 Puljak, 2016). The change scores with the corresponding standard deviations were used, as based the Cochrane handbook 192 on guidelines of the 193 (https://www.cochranelibrary.com/cdsr/doi/10.1002/14651858.CD012276/epdf/full).

194

# 195 **2.3 Data analysis**

196 All of these meta-analyses were conducted using the Review Manager (RevMan) software, 197 version 5.3. (Copenhagen: The Nordic Cochrane Centre, The Cochrane Collaboration, 2014; http://tech.cochrane.org/revman). The data type was selected as continuous. The statistical 198 199 method was considered as inverse variance. Weighted means, effect sizes, 95% confidence 200 intervals (CIs), which included 0, were calculated. In all of these analyses, P-value <0.05 was considered statistically significant. Differences among the groups were defined when the 95% 201 CIs overlapped a vertical line. If the 95% CIs did not overlap, it can be suggested that the 202 203 differences were significant (Yang, Scott, Mao, Tang, & Farmer, 2014; Dardiotis et al., 2018). 204 The studies are presented as Forrest plots in the order of the statistical power.

205

# **RESULTS OF THE REVIEW**

### 207

# 3.1 Chitosan-microbe interactions

The antimicrobial activity of chitosan is a complex process that depends significantly from intrinsic properties and environmental factors (Yilmaz Atay, 2019) as well as the type of bacteria, fungi or virus involved (Chirkov, 2002; Kong, et al., 2010; Hosseinnejad, & Jafari, 2016). The precise mechanism of chitosan antimicrobial activity is still not completely

understood. Several studies have suggested that the antimicrobial action is mainly due to the 212 213 polycationic structure of the chitosan. Several studies have suggested that the antimicrobial 214 action is mainly due to the polycationic structure of the chitosan. This activity is carried out in a pH range among 5.6 and 6 (Romanazzi, Gabler, Margosan, Mackey, & Smilanick, 2009) that 215 216 is below the pKa of chitosan. The chitosan, positively charged, reacts with negatively charged microbial cell membranes (Rabea, Badawy, Stevens, Smagghe, & Steurbaut, 2003; Goy et al., 217 218 2009; Kong et al., 2010). This bond alters the permeability of the membrane which is followed by an inhibition of DNA replication and subsequently cell death (Nagy et al., 2011; Divya, 219 Vijayan, George, & Jisha, 2017). A chelating action was also observed. The chitosan molecule 220 221 binds to the metallic elements present in the trace causing the inhibit of toxins production and 222 microbial growth (Cuero, Osuji, & Washington, 1991; Chung, Wang, Chen, & Li, 2003). The effect of chitosan on fungal pathogens was to inhibits the radial growth, spore germination, and 223 224 the elongation of the germ tube as well as the production of virulence factors (Palma-Guerrero, Jansson, Salinas, & Lopez-Llorca, 2008; Badawy, & Rabea, 2011). 225

226

227 **3.2** Chitosan-plant interactions

The chitosan acts as a powerful elicitor able to inducing a defense response against pathogens 228 in plant tissues by activating both, a local (Zuppini et al., 2003; Iriti, & Varoni, 2015) and 229 230 systemic plant defense (Benhamou, Lafontaine, & Nicole, 1994; Xing, Zhu, Peng, & Qin, 2015) with the involvement several molecules related to defense mechanisms as pathogenesis-related 231 (PR) proteins (Lopez-Moya et al., 2017; Corsi, Forni, Riccioni, & Linthorst, 2017), Reactive 232 Oxygen Species (ROS) (Singh et al., 2019) and secondary metabolites with active roles in 233 defense as lignin, callose, phytoalexins, PAL, peroxidases and chitinase (Ma, Yang, Yan, 234 Kennedy, & Meng, 2013; Landi et al., 2014; Malerba, & Cerana, 2016). However, the chitosan 235 236 elicitation activity depends on the reactivity of the host tissues (Romanazzi et al., 2016) as well

as from the acetylation and degree polymerization of chitosan (Cord-Landwehr, Melcher, 237 238 Kolkenbrock, & Moerschbacher, 2016; Li, Xing, Liu, & Li, 2016). Until now the chitosan binding receptors are undefined (Iriti & Faoro 2009; Hidangmayum, Dwivedi, Katiyar, & 239 Hemantaranjanm, 2019). Some researches proposed that chitosan could also interact with 240 chromatin and directly affect gene expression (Hadwiger & Polashock, 2013; Katiyar, 241 Hemantaranjan, Bharti, & Nishant Bhanu, 2014). However, chitosan molecular signals are 242 transduced by messengers such as ROS or phytohormones able to induce physiological and 243 defense response by host (Yin, Li, Zhao, Du, & Ma, 2006; Hidangmayum et al., 2019). 244

An effect often observed on plants tissue after chitosan treatment was the inhibition of light-induced stomatal opening (Lee et al., 1999; Iriti et al., 2009). On this regard, the transcriptome analysis performed on sweet orange (Coqueiro et al., 2015) and strawberry (Landi et al., 2017) after chitosan treatments underline early impact of compound on the light photosynthetic process affecting imbalance/balance of ROS/redox signaling (Landi et al., 2017). These entire signaling molecules contribute to the adaptive mechanism in chitosan treated plants in response to stress.

252

253 **3.3 Description of included studies** 

254 A flow chart of the screening of the studies identified for the effectiveness of 1% chitosan is shown in Figure 1, with a total of 56 articles finally available for the meta-analysis according 255 to the search criteria. These covered 117 studies, of which 49 were related to disease incidence 256 257 (total cases, 8,543 [for each of control and chitosan treatment]) (Figure 2), 41 to in-vitro mycelium growth (total cases, 1,072) (Figure 3), and 27 to changes in defence-mechanism-258 259 related enzymes (total cases, 1,332) (Figure 4). Some of the relevant details of the articles that were included in this meta-analysis are given in Table 1. All of the selected articles were 260 included in the assessment for risk of bias. Also, blinding of outcome assessment in these 261

studies (i.e., performance bias) was not necessary, so it was not included in the analysis for risk 262 of bias. The domains considered for risk of bias were chosen based on each study that reported 263 data and scientific information. All of the studies provided specific indication that the basic 264 characteristics of the control and treatment groups were balanced and were treated under similar 265 environmental conditions. None of these studies included misleading samples. As a result, the 266 selection, detection, attrition and reporting were free of bias, and the publications were defined 267 as at low risk of bias. The funnel plots constructed from the data for disease incidence, 268 mycelium growth and defence enzyme activities did not reveal any significant asymmetry 269 (Figure 5). 270

271

#### 272 **3.4 Effects of 1% chitosan on disease incidence**

Based on this meta-analysis, the overall data demonstrated the significant effectiveness of 1% 273 chitosan over the control treatment for reduction of disease incidence (studies, 49; total cases, 274 8,5473) (mean difference [MD], -30.22; 95% confidence intervals [CI], -36.48 to -23.96; I<sup>2</sup>, 275 90.0%; P <0.00001) (Figure 2). The subgroup analysis here (Figure 2) showed that 1% chitosan 276 was significantly effective for reduction of disease incidence against: gray mold (studies, 12; 277 total cases, 1,473), (Shao, Tu, Tu, & Tu, 2012; Feliziani, Santini, Landi, & Romanazzi, 2013; 278 279 Gao, Zhu, & Zhang, 2013; Romanazzi, Feliziani, Santini, & Landi, 2013; Feliziani et al., 2015; Kanetis, Exarchou, Charalambous, & Goulas, 2017; Zheng, et al., 2017; Gramisci, Lutez, 280 Lopes, & Sangorrína, 2018; Hajji, Younes, Affes, Boufi, & Nasri, 2018) (MD, -23.97; 95% CI, 281 -32.25 to -15.68; I<sup>2</sup>, 77.0%; P < 0.00001), as highly effective in 9 of these studies, (Shao et al., 282 2012; Gao et al., 2013; Romanazzi et al., 2013; Feliziani et al., 2015; Kanetis et al., 2017; 283 Zheng, et al., 2017; Gramisci et al., 2018; Hajji et al., 2018); blue/green molds caused by 284 Penicillium spp. (studies, 16; total cases, 1,968) (Xing, Xu, Che, Li, & Li, 2011; Shao et al., 285 2012; Cháfer, Sánchez-González, González-Martínez & Chiralt, 2012; Feliziani et al., 2013; 286

Romanazzi et al., 2013; Wang, Wu, Qin, & Meng, 2014; Lu et al., 2014; Shao et al., 2015; El 287 288 Guilli, Hamza, Clément, Ibriz, & Ait Barka, 2016; Zheng, et al., 2017; Gramisci et al., 2018; Kharchoufi, et al., 2018; Liu, Sun, Xiu, Huang, & Zhou, 2018; Shi, Wang, Lu, & Deng, 2018) 289 (MD, -30.85; 95% CI, -41.91 to -19.79; I<sup>2</sup>, 90.0%; P <0.00001), as highly effective in 9 of 290 these studies (Xing et al., 2011; Romanazzi et al., 2013; Lu, et al., 2014; Shao et al., 2015; El 291 Guilli et al., 2016; Zheng, et al., 2017; Liu et al., 2018; Shi et al., 2018); *Rhizopus* rot (studies, 292 293 5; total cases, 1,740) (Cia, Benato, Pascholati, & Garcia, 2010; Ramos-García et al., 2012; Romanazzi et al., 2013; Xing et al., 2015) (MD, -28.80; 95% CI, -46.13 to -11.47; I<sup>2</sup>, 87.0%; 294 P = 0.001), as effective in 3 of these studies (Cia et al., 2010; Ramos-García et al., 2012; 295 296 Romanazzi et al., 2013); and anthracnose (11 studies; total cases, 2,134) (Magbool, Ali, 297 Ramachandran, Smith, & Alderson, 2010; Zahid, Ali, Manickam, Siddiqui, & Maqbool, 2012; Bill et al., 2014; Edirisinghe, Ali, Maqbool, & Alderson, 2014; Ali, Noh, & Mustafa, 2015; 298 299 Gutiérrez-Martínez, Bautista-Banos, Berúmen-Varela, Ramos-Guerrero, & Hernández-Ibanez, 2017; Obianom et al., 2019) (MD, -46.64; 95% CI, -61.54 to -31.73; I<sup>2</sup>, 92.0%; P <0.00001), 300 as effective in all of these studies. For Alternaria rot, 1% chitosan was not significantly effective 301 (studies, 5; total cases, 1,228) (Meng, Yang, Kennedy, & Tian, 2010; Yan et al., 2011; López-302 303 Mora, Gutiérrez-Martínez, Bautista-Baños, Jiménez-García, & Zavaleta-Mancera, 2013; 304 Feliziani et al., 2015; Guo, Xing, Yu, Zhao, & Zhu, 2017) (MD, -8.50; 95% CI, -15.75 to -1.25;  $I^2$ , 27.0%; P = 0.24), although in 1 of these studies (Guo et al., 2017) its effect reached 305 significance. 306

307

# 308 **3.5 Effects of 1% chitosan on in-vitro mycelium growth**

The overall data here showed the significant effectiveness of 1% chitosan over the control treatment against *in-vitro* mycelium growth of these fungal pathogens that are involved in postharvest diseases (studies, 41; total cases, 1,072) (MD, -54.32; 95% CI, -64.35 to -44.28;

 $I^2$ , 95.0%; P <0.00001) (Figure 3). The subgroup analysis here (Figure 3) showed that 1% 312 313 chitosan was significantly effective against *in-vitro* mycelium growth for: *B. cinerea* (studies, 5; total cases, 37) (Kanetis et al., 2017; Xu et al., 2007; Feliziani et al., 2013; Munhuweyi et al., 314 2017; Flores et al., 2018). (MD, -49.38; 95% CI, -72.98 to -25.79; I<sup>2</sup>, 94.0%; P <0.0001), as 315 medium high effects for all of these studies; Penicillium spp. (studies, 9; total cases, 65) (Xing 316 et al., 2011; Abdel-Kader, El-Mougy & Lashin, 2011; Nisia, Noreña, & Brandelli, 2012; Wang 317 318 et al., 2014; Waewthongrak, Pisuchpen, & Leelasuphakul, 2015; Shao et al., 2015; Munhuweyi et al., 2017; Madanipour, et al., 2019) (MD, -73.00; 95% CI, -89.71 to -56.30; I<sup>2</sup>, 92.0%; P 319 <0.00001), as the highest effects seen, and for all of these studies; *Colletotrichum* spp. (studies, 320 321 24; total cases, 955) (Jitareerat, Paumchai, Kanlayanarat, & Sangchote, 2007; Rahman, 322 Mahmud, Kadir, Abdul Rahman, & Begum, 2008; Munoz, Moret, & Garces, 2009; Maqbool et al., 2010; Zahid et al., 2012; Mohamed, Clementine, Didier, Gérard, & Noëlle, 2013; Ali et al., 323 2014; Bill et al., 2014; Edirisinghe et al., 2014; Ali et al., 2015; Varela, Coronado Partida, 324 Ochoa Jiménez, López, & Martínez, 2015; Gutiérrez-Martínez et al., 2017; de Oliveira, Berger, 325 de Araújo, Camara, & de Souza, 2017; Ramos-Guerrero, González-Estrada, Hanako-Rosas, & 326 Bautista-Banõs, 2018; Xoca-Orozco, Aguilera-Aguirre, López-García, Gutiérrez-Martínez, & 327 Chacón-López, 2018) (MD, -48.18; 95% CI, -62.83 to -33.53; I<sup>2</sup>, 96.0%; P <0.00001), as the 328 329 lowest effects seen based on the point estimate, with the highest effects for 16 of these studies (Jitareerat, et al., 2007; Rahman, et al., 2008; Magbool et al., 2010; Zahid et al., 2012; Bill et 330 al., 2014; Ali et al., 2014; Varela et al., 2015; de Oliveira et al., 2017; Ramos-Guerrero et al., 331 2018; Xoca-Orozco et al., 2018); and Alternaria spp. (3 studies; total cases, 15) (Yan et al., 332 2011; Feliziani et al., 2013; López-Mora et al., 2013) (MD, -55.20; 95% CI, -80.50 to -29.90; 333  $I^2$ , 90.0%; P <0.0001), as significant for all of these studies. 334

335

## 336 **3.6 Effects of 1% chitosan on enzyme activities associated with host defence**

The overall data for the effects of 1% chitosan on the activities of the enzymes associated with 337 338 host plant defence at 24 hpt showed significantly increased activity over the control treatment (studies, 27; total cases, 1,332) (MD, 74.58; 95% CI, 41.15 to 108.01; I<sup>2</sup>, 99.0%; P < 0.0001) 339 (Figure 4). For the details of the subgroup analysis here (Figure 4), in the treated fruit, 1% 340 chitosan did not induce any significant difference compared to the control at 24 hpt for the PAL 341 activity (studies, 9; total cases 575) (Zahid et al., 2012; Landi et al., 2014; Bill et al., 2014; Shao 342 et al., 2015; Waewthongrak et al., 2015; Song et al., 2016; Jongsri, Rojsitthisak, 343 Wangsomboondee, & Seraypheapa, 2017; Shen & Yang, 2017; Silva et al., 2018) (MD, 37.06; 344 95% CI, -17.28 to 91.40; I<sup>2</sup>, 99.0%; P = 0.18). However, 5 of these studies (Landi et al., 2014; 345 346 Bill et al., 2014; Shao et al., 2015; Waewthongrak et al., 2015; Shen & Yang, 2017) showed significant increases in PAL activity. Furthermore, significant increases were seen overall for 347 chitinase activity (10 studies; total cases, 491) (Hewajuliage, Sultanbawa, Wijeratnam, & 348 349 Wijesundara, 2009; Feliziani et al., 2013; Bill et al., 2014; Landi et al., 2014; Ali et al., 2014; Shao et al., 2015; Jongsri, et al., 2017; Shen, & Yang, 2017) (MD, 75.95; 95% CI, 36.18 to 350 115.73;  $I^2$ , 99.0%; P = 0.0002), as 8 of these with significance increases (Hewajuliage, et al., 351 2009; Feliziani et al., 2013; Landi et al., 2014; Bill et al., 2014; Ali et al., 2014; Jongsri, et al., 352 353 2017; Shen, & Yang, 2017), and overall for  $\beta$ -1,3-glucanase activity (8 studies; total cases 266) 354 (Hewajuliage, et al., 2009; Wang & Gao, 2013; Landi et al., 2014; Bill et al., 2014; Ali et al., 2014; Shao et al., 2015; Jongsri, et al., 2017; Shen, & Yang, 2017) (MD, 115.06; 95% CI, 355 38.24 to 191.88;  $I^2$ , 100.0%; P = 0.003), as 5 of these with significance increases (Hewajuliage, 356 et al., 2009; Wang & Gao, 2013; Landi et al., 2014; Bill et al., 2014; Ali et al., 2014). 357

358

# 359 4 **DISCUSSION**

This study brings together and summarises the results from the literature of the effects of 1% chitosan on postharvest diseases and pathogens, according to disease incidence, *in-vitro* 

mycelium growth, and induction of host defence responses through monitoring of the most 362 commonly analysed enzymes linked to defence mechanisms. This meta-analysis emphasises 363 the primary role of 1% chitosan against the main diseases and pathogens associated with 364 postharvest decay (Romanazzi et al., 2018; Betchem et al., 2019). These pooled estimates 365 highlighted that 1% chitosan is effective against the main postharvest diseases caused by several 366 fungal pathogens that infect different plant species. Although some of these data show high 367 heterogeneity, they also show low risk of bias and high validity for each study, with no 368 substantial baseline differences seen between the control and treatment groups. Indeed, the 369 funnel plots as a method to assess the potential role of publication bias (Harbord, Egger, & 370 371 Sterne, 2006) indicate that no bias was detected across the studies included. Therefore, these 372 values of  $I^2 > 90\%$  indicate real differences in these studies.

Our study underlines the transversal effectiveness of chitosan in postharvest disease management. Here, the subgroup analysis of *in-vitro* mycelium growth emphasises that the most powerful growth reduction was for *Penicillium* spp., followed by *Alternaria* spp. and *B. cinerea*, while lower effectiveness was seen against *Colletotrichum* spp..

These data also show that chitosan has differential effects across these fungal species, 377 378 potentially through the control of fungal development and lytic enzyme activation by chitosan 379 (El Gueddari, Rauchhaus, Moerschbacher & Deising, 2002; Geoghegan & Gurr, 2016; Geoghegan, Steinberg, & Gurr, 2017; Ramos-Guerrero et al., 2018; Ramos-Guerrero, 380 González-Estrada, Romanazzi, Landi, & Gutiérrez-Martínez, 2020). There are direct links 381 382 between the cell wall and cell membranes, as the synthesis of key cell-wall components (e.g., glucans, chitin) occurs at the plasma membrane, with the associated synthase enzyme 383 384 complexes (Maddi, & Free, 2010). The chitin is localized in the membrane proximal portion of the cell wall and is incorporated into the wall matrix by being cross-linked to the glucans (Patel 385 & Free, 2019). Previous studies have investigated the role of plasma membrane in the sensitivity 386

of fungi to chitosan showing that the plasma membrane of chitosan-sensitive fungi is more fluid and richer in polyunsaturated free fatty acids than in chitosan-resistant fungi (Palma-Guerrero et al., 2009 and 2010). The authors evidenced that chitosan binds to negatively charged phospholipids. This alter plasma membrane fluidity to inducing the membrane permeabilization, which was greatest in membranes containing elevated content polyunsaturated lipids.

While this meta-analysis highlights the different reactions between the fungal species and chitosan effectiveness, it also underlines the key role of plant species in this complex relation that significantly affects the outcome of chitosan-pathogen interaction.

396 For this reason, the fungal pathogens can react differently to chitosan in terms of disease 397 incidence and in *in-vitro* tests. Indeed, the meta-analysis summarized studies related to disease incidence, show significantly reducing postharvest disease incidence, although the results 398 399 linked to singular disease show the highest effectiveness of chitosan against anthracnose, while it is less effective against blue/green mold, Rhizopus rot, gray mold, and particularly Alternaria 400 401 rot. Therefore, it is not excluded that the involvement of mainly different fruits species on anthracnose incidence, as banana, papaya, dragon, bell pepper, soursop and avocado, not tested 402 403 for the other diseases, the chitosan, could be elicited a different defence response.

404 This study also confirms that disease incidence is the result of a combination of the 405 chitosan effects on film-forming, plant defence eliciting, and its antimicrobial properties (Romanazzi et al., 2018). In this context, chitosan can be considered to be a modulator of plant 406 407 defences (Lopez-Moya, Suarez-Fernandez, & Lopez-Lorca, 2019). Chitosan application to plants fits into the delicate relationship between the host and pathogenic fungi and involves the 408 409 primary cell-wall defence mechanisms. A link between pathogenicity and the enzymes that synthesise the fungal cell wall has been demonstrated in numerous studies (Arana et al., 2009; 410 Levdansky et al., 2010; Lenardon, Munro, & Gow, 2010; Oliveira-Garcia, & Deising, 2013; 411

Geoghegan et al., 2017; Patel & Free, 2019), and depolymerisation of the cell walls of plant pathogenic fungi following the infection, evading plant immune recognition, has been reported (Geoghegan et al., 2017). It has been reported that the strategy of some fungal pathogens to evade plant immunity is to convert chitin into chitosan (Lopez-Moya, et al., 2019). Thus, both chitosan and chitin will have key roles in the control of plant immunity.

According to the concepts of systemic acquired resistance (Pieters et al., 1998; Durrant 417 418 & Dong, 2004) and induced systemic resistance (Heil & Bostock, 2002; Timmermann, 419 González, & Ruz, 2020), chitosan can induce resistance in the plants to control postharvest fungal pathogens of their fruit and as vegetables (Nandeeshkumar et al., 2008; Jia, Meng, Zeng, 420 421 Wang, & Yin, 2016; Jia, Zeng, Wang, Zhang, & Yin, 2018). On this basis, the meta-analysis 422 data related to the eliciting of the host defence enzymes by chitosan through activation of induced resistance can help us to understand this aspect (Mandal, Kar, Mukherjee, & Acharya, 423 424 2013; Walters, Ratsep, & Havis, 2013).

Although a meta-analysis of publicly available data, related to transcriptome 425 investigations of plants defense priming, evidenced a common set of conserved transcriptional 426 changes on plants upon stress conditions, (Baccelli, Benny, Caruso, & Martinelli, 2020), the 427 428 detailed role of the chitosan in the induction of defence mechanisms has been shown for sweet 429 oranges (Coqueiro et al., 2015) and strawberries (Landi et al., 2017). The most common approaches related to the study of enzyme activities (Wang & Gao, 2013; Ali et al., 2014; 430 Pasquariello et al., 2015; Shao et al., 2015; Adiletta, Zampella, Coletta, & Petriccione, 2019) 431 and the expression of individual genes (Ma et. al., 2013; Landi et al., 2014; Petriccione et al., 432 2017; Fooladi vanda, Shabani, & Razavizadeh, 2019; Chun & Chandrasekaran, 2019) have 433 434 been investigated, both of which are associated with reactive oxygen species, specific PR proteins, cell-wall enzymes and secondary metabolites. Usually, these individual studies have 435

shown wide variability associated with host fruit species, application methods and times oftreatment.

In the present study, we analysed the most studied of the plant defence enzymes, PAL, 438 which is associated with the phenylpropanoid pathway (Dixon, Lapthorn, & Edwards, 2002; 439 Yadav et al., 2020), and chitinase and  $\beta$ -1,3-glucanase, which are linked to cell-wall hydrolysis 440 (Gupta et al., 2015; Pusztahelyi, 2018), at the main analysis time point of 24 hpt. These data do 441 not show any significant effects of chitosan on PAL activity at 24 hpt, while high increases in 442 the activities of chitinase and  $\beta$ -1,3-glucanase were detected, independent of the host species. 443 These findings are in agreement with the plant immunity mechanisms that indicate that 444 445 chitinase and  $\beta$ -1,3-glucanase release the glucan oligomers from the chitin of the fungal cell 446 walls to trigger the plant immune responses (Jones & Dang, 2006; Fesel & Zuccaro, 2016; Lopez-Moya et al., 2019;), although the induction of these defence mechanisms can vary greatly 447 448 according to the time of treatment. The present study suggests that the analysis of the chitinase and  $\beta$ -1,3-glucanase activities at 24 hpt represents a marker for verification of induction of the 449 plant defences by chitosan, while activation of PAL has generally been reported to occur at later 450 times (Landi et al., 2014; Bill et al., 2014). 451

452

#### 453 **5 CONCLUSIONS**

The present work established the first comprehensive investigation of chitosan effectiveness on postharvest pathogens using meta-analysis approach. This study provides knowledge based on three robust findings, as the effects of 1% chitosan on disease incidence, mycelium growth of decay-causing fungi, and the activities of two important defence enzymes in particular, chitinase and  $\beta$ -1,3-glucanase. This investigation shown the chitosan have antifungal properties against different phytopathogens highlight the versatile properties of this natural biopolymer. 460 It was demonstrated there are enough data about the effectiveness of chitosan in the control of461 postharvest diseases, also inducing resistance on fruit to postharvest pathogens.

The outcomes of this study aim to contribute to a better understanding concerning the role of chitosan in the control of postharvest decay of fresh fruit, that will be relevant for the conceptualization and measurement of future studies. Collectively, these data confirm the multiple mechanisms of action of chitosan, which has unique properties in the panorama of activities of natural compounds that define it as a model plant-protection agent for sustainable control of postharvest decay of fruit and vegetables.

1112	Acknowledgements

1113 The authors would like to thank COST Action FA1405 "Using three-way interactions between 1114 plants, microbes and arthropods to enhance crop protection and production" for organising a 1115 meta-analysis workshop in July 2016, from led to the idea for this study.

1116

## 1117 Author Contributions

R.R. performed the literature research, analysed the data, and contributed to write the
manuscript; L.L designed the analysis, analysed the data, and wrote the manuscript; G.R.
designed the analysis, supervised and complemented the writing, and coordinated the study.

1122 **Conflicts of Interest:** The authors declare that they have no competing interests.

Figure 2. Forest plots using the RavMan 5.3 software for random effects analysis related to the effectiveness of 1% chitosan on disease incidence. Gray mold, blue/ green mold, *Rhizopus* rot., anthracnose and *Alternaria* rot were considered as subgroups. For Feliziani 2013, Kanetis 2017, Lu 2014, Shao 2012, Ramos-Garcia 2012, Gutièrrez-Martinez 2017 and Zahid 2012, several studies were included from each article into the subgroups. IV, inverse variance; CI, confidence interval.

Figure 3. Forest plot using the RavMan 5.3 software for random effects analysis related to the effectiveness of 1% chitosan on *in-vitro* mycelium growth. *Botrytis cinerea*, *Penicillium* spp., *Colletotrichum* spp. and *Alternaria* spp. were considered as subgroups. For Kanetis 2017, Kader 2011, de Oliveria 2017, Gutièrrez-Martinez 2017 and Zahid 2012, several studies were included from each article into the subgroups. IV, inverse variance; CI, confidence interval.
